EYRE AND SPOTTISWOODE, HER MAJESTY'S PRINTERS,  
EAST HARDING STREET, FLEET STREET, E.C.

# Journal of the Society of Chemical Industry.

## INDEX OF VOL. XIII.—1894.

### INDEX OF AUTHORS' NAMES.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a Patent.

		PAGE
<b>A</b>		
Abbott, W., and Wilks, W. R. Rubber-coated Waterproof Fabrics (P).....		248
Abney, W. de W. See Hummel.....		803
Abou, J. W. Bleaching Paper Pulp, &c. (P).....		834
Abraham, K. Use of Sulphurous Acid in Sugar Manufacture.....		165
Abraham, E. See Fenn.....		896
Acheson, E. G. Carbons for Electric Lamps, &c. (P).....		1207
Ackerman, P. The Substantive Dyestuffs in the Dyeing of Half-Wool Goods.....		386
Aetion Gesellschaft für Anilin Fabrikation, Manufacture of 2:7-Amido-naphtholdisulpho Acid and Colouring Matters therefrom (P).....		876
Manufacture of a New Amidonaphtholdisulphonic Acid (P).....		32
Manufacture of Basic Colouring Matters (P).....		511
Manufacture of Colouring Matters (P).....	246, 724,	1189
Manufacture of Mordant-dyeing Colouring Matters (P).....		723
Manufacture of New Bases and their Sulpho Acids (P).....		1055
Photographic Developers (P).....		459
Aetion Maschinenbauanstalt vorm. Venueth and Ellenberger. Process and Apparatus for Drying and Treating Distillers' Washes (P).....		827
Adam, P. Sodium Boro-Salicylate.....		834
The Emetics.....		1216
Addie, J., and others. Production of Cyanides (P).....		635
Adeney, W. E., and Parry W. K. Purification of Sewage and other Liquids (P).....		831
Adkins, J. J. Treating Brewers' Spent Hops for Production of Fodder and Litter (P).....		168
Aguillon, M. Heat of Combustion of Coal-Gas, and its Relations to Lighting Power.....		26
Aitken, A. P. Rapid Method of Determining Moisture and Oil in Linseed Cakes, &c. (illus.).....		469
Aitken, H. Apparatus for obtaining Cyanogen, Cyanides, &c. (P) (illus.).....		517
Albright, G. S., and Hood, J. J. Manufacture of Manganese Peroxide (P).....		517
Alexander, H. Apparatus for Electro-Deposition of Metals (P).....		819
Allein and Gaud. Estimating Cupric Reducing Power.....		1229
Allen, A. H. Discussion on Commercial Analysis of Lard.....		708
Discussion on Estimation of Tanning Matter.....		495
Allen, C., and Davy, C. Apparatus for Manufacture of Cast Iron and Steel (P).....		815
Allen, C. M. Processes and Converters for Smelting and Refining Ores.....		1203
Allen, S. Filtering Apparatus (P).....		378
Allen, W. Apparatus for Heating by Creosote, &c. (P) (illus.).....		1050
Alliott, J. B., and Paton, J. McC. C. Furnaces for Burning Refuse (P) (illus.).....		898
Allison, T. R. Extract of Cocoa (P).....		56
Allison, W. O. See Pennington.....		725
Altschul, M., and Meyer, V. The Chlorination of Ethyl Alcohol.....		415
Amend, O. P. Improvements in Dyeing (P).....		151
Ammann, K. Washing Blue (P).....		1209
Anderlik. Mucilaginous Beet Juice.....		749
Anderson, G. R., and others. Artificial Asphaltum or Pitch, and Process of Making Same (P).....		740
Anderson, J., jun. Apparatus for Separating Foreign Matter from Waste Rubber, Bark, Grain, &c. (P).....		974
Andersson, H. K., and Sjöström, D. Disinfecting Apparatus (P).....		900
Andiran, A. J. J. d'. See Durand.....	145, 146, 247, 802,	1055
Andreoli, E. Electrical Production of Ozone and Luminosity (P).....		162
Electrolytic Apparatus (P).....		190
Andresen, M. Development of Photographs (P).....		1249
Andrews, T. Effect of Stress on Corrosion of Metals.....		1266
Angele, W. Manufacture of Soluble Starch (P).....		765
Angell, A. Manufacture of Oil Paints and Compositions (P).....		803
Anning, J. J. Iodine Liniment (P).....		836
Antal, J. Cobalt Nitrate an Antidote for Cyanide Poisoning.....		1106
Antonchevitch, A. See Sahanejeff.....		1676
Appert, L. Engelmann's Process for Decoration of Glass.....		1197
Archbutt, L., and Deeley, R. M. Purification of Sewage (P).....		899
Armstrong, M. M. Method and Furnaces for Smokeless Combustion (P) (illus.).....		761
Arnaudon, J. J. Vegetable Silks, particularly the Kapok of India.....		247
Arnold, J. O. The Physical Influence of Elements on Iron.....		642
And Read, A. A. Conditions in which Carbon exists in Steel.....		740
Arnold, W. Apparatus for Washing Filtering Media (P) (illus.).....		16
Arquembourg, H. See Grouvelle.....		950
Arth, G. Experiments on Coals immersed in Water.....		1352
Artiques. A New Photographic Printing Paper.....		720
Artus, C. Treatment and Preparation of Alimentary Fats and Compounds (P).....		969
Aseough, J. Manufacture of Sodium Bifluoride (P).....		1297
Ash, C. A. Apparatus to Enable a Person to Breathe Fresh Air while Surrounded by a Noxious Atmosphere (P).....		733
Ash, T. M., and others. Coating Non-metallic Articles with Metal (P).....		501
Ashcroft, E. A. Process and Apparatus for Treating Refractory Ores (P).....		57
Ashworth, A., and Burger, J. Production of Colouring Matters (P).....	691, 723,	
Aspinall, F. B., and others. Bleaching, Sweetening, &c. Oils and Fats (P).....		1298
Atlass, E. See Lehl.....		51
Aubry, L. Composition of Hops, and their Influence on Wort.....		177
Composition of Hops, and Influence of Hops on Wort.....		411
The Composition of Hops, and their Relation to Wort.....		895
Auer, H. See Hurler.....		978
Autenrieth, W. Yellow Prussiate of Potash, and Detection of Hydrocyanic Acid.....		843
Axedorfer, G., and Sasse, C. F. H. Apparatus for Mixing Gas and Air (P).....		1620

	PAGE		PAGE
Barnheim, L., and Jernander, A. Electric Lignating Compound (P).....	561	Bartlett, G. See Peptine Maltine, Lim. ....	1083
Bach, A. Action of Light on Phenol.....	988	Baschmakoff, S. de. See Nalcin.....	58
Ba h. O. Valuation of Zinc Dust.....	765	Basle Chemical Works Rindschidler. Manufacture of a New Dioxynaphthalene-mono-sulpho Acid and Colouring Matters therefrom (P).....	632
Bachofen, F. See Lunge.....	36	Manufacture of a New Dioxynaphthoic-mono-sulpho Acid, and Colouring Matters therefrom (P).....	632
Baltische Anilin und Soda Fabrik. Manufacture of Alpha-beta-methyl-eurhodines (P).....	879	Bates, F. G. Baths for Treating Iron or Steel (P).....	645
Manufacture of Aurumine (P).....	217	Bateson, P. Discussion on Manufacture of Straw Cellulose.....	197
Manufacture of Basic Colouring Matters (P).....	723	Battut, Control of Beetroot Sugar Manufacture.....	759
Manufacture of Beta-methyl-eurhodine (P).....	878	Bau, A. Estimation of Succinic Acid formed in Fermentations.....	287
Manufacture of Colouring Matters (P).....	1189	Baum, H. Manufacture of Orthohalogen-phenol, and Pyrocatechine therefrom (P).....	658
Manufacture of Colouring Matters and Intermediate Products (P).....	1191	Baum, J. H. Production of Pyrocatechine (P).....	579
Manufacture of Dihydroxy-naphthalene-sulpho Acids and Corresponding Azo Dyes (P).....	942	Baumann, T. Report on Petzold's Paper on "A New Direct Grey".....	143
Manufacture of Mordant-dyeing Colouring Matters (P).....	943	Baumbach, O. A Disinfecting Oven (P).....	413
Manufacture of New Colouring Matters from Naphthalene (P).....	650	Baumert, P., and Peck, A. Artificial Stone and Marble (P).....	413
Manufacture of New Dyes of the Phenanthrene Series (P).....	942	Baur, A. Bye-Products of the Preparation of Butyltoluene.....	1213
Manufacture of New Sulpho-Acids of Phenylresinduline, &c. (P).....	510	Production of Artificial Musk (P).....	903, 903
Production of a New Amido-Sulpho-Acid and Azo Dyes therefrom (P).....	724	Bayley, T. Treating Grain, &c. for Brewing (P).....	1082
Production of New Acid Colouring Matters (P).....	145, 801	Bayrac, P. Volumetric Estimation of Lead in Tin Solutions or Platings.....	429
Production of New Azo Dyes (P).....	1054	Beacham, F. C. D. Colours for, and Colouring, Photographs, &c. (P).....	759
Production of New Azo-Dyes, and Component therefor (P).....	144	Beadle, C. Commercial Cellulose Derivatives.....	960
Production of New Colouring Matters and Leuco Compounds (P).....	802	Marking Indelibly on Paper and Fabrics (P).....	1194
Production of New Compounds for Preparation of Diazo Compounds (P).....	1189	Beardmore, W. See Fairfax.....	1067
Production of New Diazo Dyes (P).....	879	Beaudet, De-fecation and Saturation.....	965
Production of New Sulpho-Acids, and New Colouring Matters therefrom (P).....	144	Beaulis, A. Report on the Mexican Leather Industry.....	992
Baerlein, M. Manufacture of Soap Compositions (P).....	962	Beck, P. Carbonic Acid Pressure Apparatus (P).....	783
And Dreyfus, C. Cleansing Mixture or Paste (P).....	939	See Freund.....	339, 540
Bacard, H. Electrical Transport of Heat in Electrolytes (illus.).....	71	Becker, American and Russian Petroleum.....	872
Bady, F. G., and Guthrie, M. Apparatus for Electrolytical Decomposition of Brine and other Liquids (P).....	818	Becker, A. See Sachse.....	409
Baines, F. E. V. Treatment of Rice and other Grain for Brewing (P).....	268	Becker, W. Process or making Leather Soft, Durable, and Waterproof (P).....	164
Baird, M. B. See Murray.....	1054	Bedford, J. E., and C. S. Manufacture of Oil Varnish and Drying Medium for Paints (P).....	863
Baker, H. Breton. The Influence of Moisture on Chemical Action.....	767	Treatment of Linseed Oil (P).....	491
Baker, R. C. Apparatus for Cooling or Warming Liquids (P).....	713	Bedson, P. P. Discussion on Lunge-Rohrman Plate Towers. Note on Poisonous Action of Lead Salts.....	1037 610
Baker, T. W. Destroying Noxious Gases from Destructors (P).....	1084	Presentation to Dr. J. T. Dunn.....	1155
Bale, F. Production of Chlorine by Ammonia-Soda Process (illus.).....	200	Behal, A., and Choay, E. Composition of Beech and Oak Creosotes.....	1157
Bale, J. H. Wafer China Mosaic (P).....	519	Qualitative Composition of Official Beech and Oakwood Creosotes.....	1087
Balke, P. On the Xanthine Bases.....	284	The Ethyl Phenols.....	794
Balland, M. On the Internal Temperature of Bread as it Comes from the Oven.....	55	Bejerinck, Butylic Alcohol Fermentation, and the Butyl Ferment.....	969
Balland and Musson. Sterilisation of Bread and Biscuits after Withdrawal from the Oven.....	169	Belby, G. Discussion on Electric Furnace for Laboratory Work.....	375
Ballantyne, H. Studies in Oil Analysis.....	1106	Discussion on Paraffin Lamp for Laboratories.....	1167
Baly, F. C., and Chorley, J. C. Thermometer for High Temperatures.....	418	Discussion on Production of Oil-Gas.....	501
Bandler, H. K. The Analysis of Steel.....	665	Belby, G. T. Proceedings of Annual General Meeting.....	693, 694
Bamberger, E., and Chittaway, F. Chrysen.....	27	Bell, A. H., and Carter, C. Apparatus for Precipitating Gold and Silver from Cyanide Solutions (P).....	816
Bamberger, M. On Xanthorrhiza Resins.....	47	Bell, J. Carter. Acknowledgment of Presentation by Manchester Section.....	608
Barber, C. M. Electro-Plating and Apparatus therefor (P).....	959	Discussion on Modern Systems of Sewage Treatment.....	609
Barber, C. See Monnet.....	658	Discussion on Sampling of Materials.....	217
Barber, C. J. Electrical Accumulator Plate (P).....	1206	Note on Estimation of Moisture in Wood Pulp.....	117
Barber, A. C. Preparation of Active Material for Accumulators (P).....	1206	Notes on the "Fertilisers and Feeding Stuffs Act".....	116
Barber, P. Geraniol.....	60	Bell, Sir L. Evaporating Saline Solutions (P).....	731
Rhodinol. The Chemical Principle of Otto's Res. ....	171	Treatment of Bicarbonate of Soda (P).....	735
And Bouveault, L. A Natural Unsaturated Ketone in Lemon-Grass Oil.....	1086	Use of Caustic Lime in the Blast Furnace.....	951
And Bouveault, L. Geraniol from Oil of Andropogon Schoenanthus.....	1086	Belloe, D., and Benard, E. Process and Apparatus for Disintegrating Cements (P).....	1198
And Bouveault, L. The Aldehyde of Lemon Grass Oil.....	1086	Belmans, L. Reducing Sulphuretted Ore into Oxides and Sulphur (P).....	153
And Bouveault, L. The Rhodinol of the Essence of Peppermint.....	1085	Benard, E. See Belloe.....	1198
Bardy, Detection of the Higher Alcohols in Spirits of Wine.....	287	Bender, Adolf. Jahres-Rundschau über die Chemische Industrie und deren Wirtschaftliche Verhältnisse für das Jahr 1893, &c.....	671
Barff, F. S., and others. Effecting the Protection of Iron and Steel Surfaces (P).....	41	Benedikt, R. Ekenberg's Process of Refining Fats, Oils, &c.....	891
Barillot, E. A New Reaction of Colehema.....	1099	And Zikes, H. Estimation of Chlorine in Fats.....	954
Barnett, H. T. Carbon Electrodes (P).....	44	Berens, H. See Lach.....	821
Platinised Electrodes (P).....	44	Benker, F. Preparation of Ammonium Nitrate (P).....	515
Barnett, A. A., and Hill, A. J. H. Separating Gelatine Films from Celluloid Supports (P).....	1088	Bennett, R. G. Composition of Varnish (P).....	1209
Bartel, A. See Schroeder.....	649, 1191, 1227	Benneville, J. S. de. Analysis of Pig-Copper, Brasses, and Bronzes.....	667
Bartle, L. Estimation of Salicylic Acid and Salicylates.....	1105	Laboratory Notes.....	667

	PAGE		PAGE
Berthelot, M. Composition of Newly-discovered Ancient Copper.....	1198	Bird, T. Inversion of Sugar by Glycerol.....	1211
Heating and Spontaneous Combustion of Hay.....	1196	Borecki, S., and Kohn's stick, J. Boiler Incrustation Fluid-P.....	711
Observations on Le Blanc's Paper on Minimum E.M.F. required to Decompose Electrolytes.....	742	Borg, C. See Valters.....	78
Bertram, J. Manufacture of Geraniol from Citronellal-ol (P).....	758	Borland, W. Apparatus for Mixing and Regulating Paper Stuff (P).....	754
And Gildenraster, E. Oil of Roses.....	834	Borntreger, A. Behaviour of Lead Acetate towards Sodium Carbonate, Sulphate, and Phosphate.....	1249
And Walbaum, H. Isoborneol.....	756	Influence of Lead Acetate on Cupric Reducing Power of Invert Sugar.....	1241
And Walbaum, H. Occurrence of Camphene in Etheral Oils.....	753	Influence of Volume of Lead Acetate Precipitate on Filtration of Sugar in Wine Analysis.....	1233
Bertrand, C. K., and Renault, B. General Characters of Bog-head Cannel.....	241	Removal of Lead from Musts and Wines.....	1250
Bertrand, E., and Thiel, O. Manufacture of Steel (P).....	846	The Volumetric Determination of Copper.....	67
Bertrand, G. The Latex of the Lacquer Tree.....	1071	Botcher, O. Detection of Adulterants in Basic Slaz.....	978
Besemfelder, E. R. Separating Metals from Ores, &c. (P).....	815	Bouchardat, G. Oil of Spike (Lavandula Spica).....	751
Bettel, Sweep Smelting and Refining Gold, Silver, and Platinum.....	953	Presence of Camphene in Essence of Lavender.....	753
Bevan, E. J. Discussion on Colorimetric Analysis.....	317, 318	Presence of Camphene in Spike Oil.....	658
Note on an Abnormal Melting Point.....	69	And Lafont, J. Synthetic Borneols.....	658
See Cross.....	334	Bouffard, A. On the "Cassage" of Wine.....	654
Beveridge, J. Discussion on Manufacture of Straw Cellulose.....	107	Bourne, See Grimoux.....	1086
The Manufacture of Straw Cellulose.....	101, 213	Bouvenot, L. See Barbier.....	1085, 1086
Beyer, A. F., and A. G. Apparatus for Treating Minerals (P).....	621	Bouvier, Filter for Diffusion Juice.....	167
Beyersack, M. W. Butyl Alcohol Fermentation and its Causes.....	167	Purification of Beetroot Juice.....	1210
Bibby, J. Machinery for Cleaning Cotton Seed (P).....	1070	Bower, G. and A. S. See Barff.....	41
Bibby, J., and J. Manufacture of Printing Ink (P).....	115	Bowing, J. Coking Processes and Apparatus, and Recovery of Products of Distillation (P).....	873
Bidet, A. Some Laboratory Apparatus (illus.).....	631	Boyd, H. A New Explosive (P).....	1219
Biedermann, R. Chemiker-Kalendar, 1895.....	1107	Boyer, L. See Levy.....	1071
Technisch-Chemisches Jahrbuch.....	845	Bracey, B. See Worsley.....	841
Bigelow, W. D. See McElroy.....	284	Bradbury, J. Apparatus and Furnaces for Concentrating Sulphuric Acid (P).....	251
Bizot, C. A Recuperative Gas Furnace (illus.).....	171	Bradley, F. J. See Hardy.....	894
Billings, A. W. Apparatus for Manufacture of Beer (P).....	896	Brain, F. W. T. Electric Fuses (P).....	790
Billings, W. A. See Warden.....	169, 169	Brand, "Maltol," as obtained from Crystallized Malt.....	891
Biltz, F. On Explosives.....	173	Brand, A. Manufacture of Chlorine (P).....	635
Binder, F. Artificial Production of Woollen Craps.....	1192	Brand, H. O. Manufacture of Parchment (P).....	1085
Bindshadler, H. See Read, Holiday and Sons.....	399	Brand, J. Malted.....	1213
Bird, T. See Hargreaves.....	250, 255, 328, 528, 886, 886, 958	Presence of Boric Acid in Beer.....	54
Birnbaum, T. Manufacture of Coloured Waterproof Fabrics (P).....	728	Brandes, W. Rectified Wood Vinegar.....	285
Bischof, G. Treatment of Lead Fumes (P).....	711	Brauns, D. Artificial Refrigeration from Central Stations.....	787
Bittel and Co. Manufacture of Filters (P).....	872	Brante and Co. Condensing Plates (P).....	931
Blackmore, H. S. Dissociating Soluble Salts by Electrolysis (P).....	257	Bredel, F. Water-gas in America.....	715
Blair, T. H. Manufacture of Photographic Films (P).....	659	Brendel, Rate of Filtration of Sugar Solutions.....	749
Blake, A. Improvement in Malting Grain (P).....	268	Brestowski, A. Handwörterbuch der Pharmacie.....	182, 768, 969
Blake, J. W., and S. J. Preservative Paints or Compositions (P).....	618	Brett, R. D. See Hill.....	153
Blake, W. P. Separation of Blende from Pyrites.....	524	Briand, L. Detection of Abstruse in Wines.....	1090
Blass, J. T. Machine for Loosening and Drying Yarns (P).....	917	Briant, L. Aeration: its Effect in Brewing.....	654
Blenkinsop, W. E. R. See Hartley.....	617	And Meacham, C. S. Hops.....	594
Bloch, L., and Schwartz, C. Azo-Colour Resists on Steam-printed Indico.....	1193	And Walker, W. H. Utilisation of Flour Rich in Diastase (P).....	55
Bloede, V. Discussion on Detection of Soap in Lubricants.....	1179	Brier, H. See The Scotch and Irish Oxygen Co.....	789
Blot, G. R. Plates for Secondary Batteries (P).....	819	Briggs, H. B. Manufacture of Condensed Milk Preparations (P).....	828
Blount, B. Discussion on Testing Hydraulic Cements.....	463	Manufacture of Condensed Milk Preparations, Invalids and Children's Foods (P).....	828
See Stancer.....	155	Brin, A. See Juhn.....	55
Bloxam, W. P. Discussion of Smokeless Powder.....	583	Brin's Oxygen Co. and Murray, K. S. Production of Oxygen from Air and Apparatus therefor (P).....	836
Blücher, H. Mantles for Incandescent Gas Lights (P).....	1182	Brintons, Linn., and Hansom, L. Machinery for Washing and Scouring Fibres (P).....	883
Boa, P. Discussion on Electric Furnace for Laboratory Work.....	376	Bristowe, L. H. Filtering Apparatus (P).....	934
Boehring, C. F., and Soehne. Manufacture of Alimentary and Medicinal Compounds (P).....	759	Broadbent, H. Discussion on Estimation of Tanning Matter.....	495
Obtaining an Iron Albumen Derivative from Animal Organs (P).....	658	Broadwell, E. C. Coating Metals with Aluminium or its Alloys (P).....	915
Bogodanoff, P. Temperature of Fusion of Tin.....	1066	Brock, J., and Hurter, F. Manufacture of Permanganates of Soda or Potash (P).....	374
Böhm, E. Manufacture of Enamel Glass Letters (P).....	1198	And others. Manufacture of Sulphocarbides and By-products, and Apparatus therefor (P).....	1195
Böhm, L. K., and Crawford, T. C. Mantles for Incandescent Gas-Burners (P).....	627	Brothers, W. Baking Powder (P).....	752
Boissien, M. P. de. Present State of the Petroleum Industry.....	791	Detergent Compound for Textiles (P).....	264
Boissien, P. de. Improvements in the Sulphuric Acid Industry (illus.).....	1057	Improved Manure or Fertiliser (P).....	160
Bokorny, T. The Physiological Action of Tellurous Acid.....	289	Brougier, A. Improving the Quality of Damaged or other Coffee (P).....	757
Bolton, W. The Weathering Properties of Sandstones.....	40	Brousse and Gay. Mercury Gallate: A New Antisyphilitic.....	171
Bona, M. D. Salicylic Acid Azo Colouring Matters. A Study on the Influence of Constitution on Fastness.....	381	Brown, A. J. Specific Character of the Fermentative Functions of Yeast Cells.....	821
Substantive Azo Colouring Matters from 1,4-Naphthylamine Sulphonic Acid (P).....	945	Brown, Cmm. Proceedings of Annual General Meeting.....	704
Bonato, P. Drinking Water Obtained from Artesian Wells at Mantua.....	752	Speech at Annual Dinner.....	704
Bandonnean, Manufacture of Potato Starch by Continuous-Flow System.....	759	Speech at Perth Banquet.....	707
Bondzynski, S. Estimation of Fat in Cheese.....	766	Brown, H. T. Proceedings of Annual General Meeting.....	709
Bonnet, A. Some Properties of Lead Oxides.....	34	Brown, J. A. See Dunn.....	1053
Bonnet, J. See Placet.....	37, 646	Brown, J. Campbell. Discussion on Aluminium Alloys.....	11
Bonnet, M. New Dyeing Process.....	726	Discussion on Inventions.....	1021
Boutemps, E. Employment of Ammoniacal Salts as Resists.....	1193	Brown, J. H. Treatment of Cuprous Iron Pyrites in Portugal.....	172
Borchers, W. Apparatus for Electrolytic Production of Metals of the Alkalies and Alkaline Earths (P) (illus.).....	159	Brown, W. A. Paste or Size for Cap Bottoms and Cotton Goods (P).....	725

Abrastol, Chemical Action of, on Wine. (Scheurer-Kestner) ..	654	
In Wine, Detection of. (Sangle-Ferrière) ..	177	
In Wines, Detection of. (Briand) ..	1099	
In Wines, Detection of. (Simbaldi) ..	548	
Note on. (Noelting) ..	534	
Acetamide, Volumetric Estimation of. (Kuster) ..	844	
Acenaphthylene, Colour of. (Grabe) ..	27	
Acetamido-Alkylsalicylic Acid, Manufacture of. (P) Abel and Imray. From Kuchler and Bull ..	60	
Acetic Acid, Apparatus for Concentrating or Vaporising. (P) Bonlt. From Peuchen and Clarke ..	251	
Acetone. (Kopp and Grandmouzin) ..	720	
Acetnaphthylene-diamine-sulpho Acids, Production of New. (P) Pitt. From Cassella and Co. ..	801	
Acetol, Manufacture of Salicylic Acid Ester of. (P) Fritsch ..	274	
Acetone and Salicylic Acid in "Sal Acetol." Quantitative Estimation of. (Eckeroth and Koek) ..	288	
And Salicylic Acid in "Sal Acetol." Quantitative Estimation of. (Helling and Passmore) ..	288	
As a Solvent. (Trimble and Peacock) ..	59	
Acetyl, Production of. (P) Von Mering ..	60	
Acetylene, Explosive Nature of. (Meyer) ..	1182	
Metallic Derivatives of. Mercuric Acetylde. (Travers and Plimpton) ..	277	
Acetylde, Mercuric. (Travers and Plimpton) ..	277	
Aceto-4-xtrin. (Lintner and Dull) ..	53	
Acid, Estimation of Free, in Solutions of Per-Salts of the Heavy Metals. (Hoffmann) ..	282	
Acidimetry, Value of Borax as the Basis of. (Salzer) ..	280	
Acidity in Worts, Influence of, on Composition of Low Wines. (Lindet) ..	52	
Acids, Alkalis and Salts. (Class VII.) 34, 151, 249, 394, 513, 634, 729, 805, 884, 947, 1057, 1057, 1195		
Action of Concentrated, on Certain Metals. (Burch and Duleson) ..	525	
Action of Salts on. (Wood) ..	515	
Action of, upon Glass. (Feierstein) ..	1099	
Afinity-Constants of Weak. (Wood) ..	826	
Apparatus for Concentrating Sulphuric, and other. (P) (Dyson) ..	1039	
Apparatus for Recovering and Concentrating Waste. (P) Levinstein ..	152	
Detection of Mineral, in Presence of Organic Acids. (Nickel) ..	423	
Detection of Mineral, in Vinograd. (Grigol) ..	423	
Estimation of the Insoluble Non-Volatile Fatty. (Mellere) ..	983	
Extraction of Pur, from Alkaline Salts. (P) Placet and Bonnet ..	37	
In Alcoholic Solution, Action of Sodium Peroxide on. (Tafel) ..	885	
Manufacture of Various, and Superphosphate of Lime. (P) Prentice ..	250	
Obtaining Sulphonic, free from Inorganic Salts. (P) Helmers ..	508	
Of Beeswax, Extraction of the Free. (Mariet) ..	1207	
Pumps for Raising. (P) Long and Burditt (illus.) ..	930	
Separation of Fatty, from Wool Fats. (P) Krause and Mayer ..	162	
The Separation of Volatile Fatty. (Wechsler) ..	178	
Aconite Alkaloids, On the. Part VIII. On Picroconitine. (Dunstan and Harrison) ..	172	
Alkaloids, On the. Part IX. The Action of Heat on Aconitine. (Dunstan and Carr) ..	172	
Alkaloids, On the. Part X. On the Conversion of Aconitine into Isaconitine. (Dunstan and Carr) ..	172	
Aconitine. (Dunstan) ..	54	
(Freund and Beck) ..	539, 540	
Action of Heat on. (Dunstan and Carr) ..	172	
Conversion of, into Isaconitine. (Dunstan and Carr) ..	172	
Address, Changes of. 3, 94, 197, 397, 447, 573, 690, 784, 868, 927, 1012, 1132		
The Presidential. (Stanford) ..	694	
To Manchester Section. (Carpenter) ..	1026	
To New York Section. (Mason) ..	1167	
To Scottish Section. (Irvine) ..	1038	
To Yorkshire Section. (Smithells) ..	18	
Advice to English Merchants. (T.R.) ..	1109	
Aeration, Effect of, in Brewing. (Briant) ..	534	
Afinity-Constants of Weak Acids. (Wood) ..	826	
Agate, Manufacture of Glass Articles Imitating. (P) Solms-Garuth ..	39	
Agave Americana Fibre ..	802	
Air and Gas, Apparatus for Mixing. (P) Axdorfer and Sass ..	1650	
Apparatus for Enabling One to Breathe Fresh, while in a Noxious Atmosphere. (P) Ash ..	793	
Apparatus for Heating. (P) Fudieker ..	1181	
Apparatus for Netifying Presence of Gases in. (P) Hardy ..	1091	
Bath, A New Form of. (Sauer) (illus.) ..	662	
Filter for. (P) Moeller ..	714	
Hydrogen Dioxide in Atmospheric. (Hosva) ..	753	
Method and Means for Supplying Sterilised, to Rooms. (P) Effront ..	833	
Or Gas, Apparatus for Carburetting or Enriching. (P) Love and Weston ..	141	
Pump, New Form of Mercury. (Kahlbaum) (illus.) ..	760	
Tanks for Storing Compressed. (P) Tiumis ..	798	
Alarm for Water Ovens and Water Baths, An Automatic. (Webster) (illus.) ..	205	
Albumen Derivative, Obtainment of, an Iron, from Animal Organs. (P) Wilcox. From Boehringer and Soehne ..	658	
Albuminoids contained in Worts and Beers. (Wahl and Hantke) ..	893	
Effect of, in Manufacture of Beer. (Wahl and Nilson) ..	896	
Albuminoses, Contribution to the Knowledge of. (Schrotter) ..	273	
Alcohol, Behaviour of Sodium Peroxide towards. (Tafel) ..	1195	
Butylic, Fermentation and the Butyl Ferment ..	969	
Determination of Oil of Turpentine in. (Perl) ..	427	
Estimation of, in Beers by Means of the Ebullioscope. (Torneo) ..	762	
Influence of, on Bactericidal Action of Phenol and Corrosive Sublimate. (Lensi) ..	903	
In Germany. (T.R.) ..	676	
In Germany, The Denaturing of. (T.R.) ..	185	
Manufacture of. (P) Lake. From Tedesco ..	896	
Preparation of, from Apples. (Vivien and Dupont) ..	902	
Production of, in Russia. (T.R.) ..	910	
Rectification of. (Sorel) ..	1081	
Alcohols, Detection of the Higher, in Spirits of Wine. (Bardy) ..	287	
Filters used in the Production of. (P) Iseli ..	377	
The Glucosides of the. (Fischer) ..	167	
Aldehyde, Manufacture of Aromatic Sulphuryl Derivatives of Proteochemie, and Conversion into Vanillin. (P) Pitt. From The Chemische Fabrik auf Aetion vormalis Schering ..	1218	
Of Lemon-Grass Oil, The. (Barbier and Bouvauit) ..	1096	
Preparation of a Crystalline Polymeric Base from Amido-Acetic. (P) Pitt. From The Chemische Fabrik auf Aetion vormalis Schering ..	1218	
Aldehydes, A Reaction of the. (Villiers and Fayolle) ..	1098	
Condensation of, with $\alpha$ -Naphthaquinone and $\alpha$ -Naphthaquinol. (Wurgitt) ..	798	
Aldoses and Cetroses, Differentiation of. (Villiers and Fayolle) ..	1098	
Algiers, Phosphate Deposits of. (T.R.) ..	1108	
Alimentary Substances. See Foods.		
Alizarin Cyanine, Dyeing Wool by Means of Alkaline Solutions of. (Schubel) ..	388	
The Formamides of. (Fruithomme and Rabaut) ..	143	
Pastes, Rapid Method of Determining Shade of. (Perkin) ..	496	
Alkali Cyanides, Production of. (P) Siepermann ..	250	
Electrolytic Production of. (P) Hargreaves and Bird ..	528	
Electrolytic Production of Caustic. (P) Vautin ..	958	
Lands in North China. (T.R.) ..	910	
Metals, Oxidation of the. (Holt and Sims) ..	926	
Method and Apparatus for Manufacture of. (P) Hargreaves and Bird ..	250	

	PAGE
<i>Alkali—cont.</i>	
Production of caustic. (P) Lange and Maxwell Lab.	734
Production of caustic and Lead Chloride. (P) Maxwell-Lange and Lange	734
Recovery of, from a Waste Product. (P) Murray and Baird	1051
Salts, Electrolytic Decomposition of. (P) Sinding Larsen	1206
Test for Kerosene, Naphtha Products, Hydrocarbon Lubricants, &c. (Lassenko and Stanawski)	177
Waste, Manufacture of Cement from. (P) Rigby, Neill, and Carr	638, 948
Works, Thirtieth Annual Report on.	729
<i>Alkalis. (Class VII.)</i>	34, 151, 249, 390, 533, 631, 729, 808, 884, 947, 1057, 1195
Action of, on Paranitrotoluene and its Sulphonic Acid. (Fischer and Hepp)	29
Decomposition of Invert Sugar by. (Prinsen-Geerlings)	119
Minimum Electro-motive Force Required for the Electrolysis of Dissolved Salts of. (Nourisson)	742
<i>Alkaloids. (Class XX.)</i>	57, 170, 272, 415, 533, 657, 755, 831, 902, 970, 1085, 1216
Conium. (Wolffenstein)	1217
From the Seeds of Lappin Albus. (Saldani)	757
German Trade in. (T.R.)	1112
In Alkaloidal Tinctures, Methods for Determination of. (Farr and Wright)	983
In Cinchona Bark, Estimation of Total. (Keller)	1101
In Nux Vomica Seeds, Estimation of. (Keller)	1105
In the Root of Corydalis Cava. (Fremd and Joseph)	59
Of Bark of Pomegranate Root. (Chamian and Silber)	116, 1217
Of Corydalis Cava, The Corydalline. (Dobije and Lauder)	1217
Of Gelsemium Sempervirens. (Cushny)	59
Of Papaveraceae. (Schmidt)	58
Of the Papaveraceae. (König and Tietz)	836
Of the Papaveraceae: Codeine. (Goehlich)	757
The Atropine. (Hesse)	416
The Estimation and Separation of the Cacao. (Kunze)	178
The Pericarp. (Hesse)	416
Allevard, Dressing Spathic Iron Ore at. (Gromier)	1044
<i>Alloy, A New Metallic. (P) Cox</i>	158
A Metallic. (P) Dixon and Skinner	957
An Aluminium. (P) Roman	956
An Improved Metallic. (P) Sage	645
Of Lead and Sodium or Potassium, Electrolytic Production of an. (P) Vautin	741
<i>Alloys, Coating Iron and Steel with. (P) Fenby and Moore</i>	400
Composition and Constitution of Certain. (C. R. Alder Wright)	1014
Electrolytic Production of Chromium. (P) Placet and Bonnet	646
For Manufacture of Wire. (P) Macdonald	523
In a Voltaic Cell, Electro-Motive Force of. (Laurie)	1204
Influence of Aluminium upon the Carbon in Ferro-Carbon. (Hogge) (illus.)	955
Manufacture and Industrial Value of Aluminium. (Daggar)	4
Manufacture of Metallic. (P) Howarth	815
Of Aluminium, Application of. (P) Taylor	42
Of Copper, On New. (Von Knerre)	815
Of Iron and Nickel. (Osmond)	649
Of Iron and Nickel, The. (Wedding)	955
On certain Ternary. Part VIII. (Alder Wright)	321
On the Cupellation of Bismuth-Silver. (Smith)	765
Pickling, to Remove Impurities. (P) Smith	526
Researches on the Properties of. (Roberts-Austen)	154
Separation and Estimation of Tin and Antimony in. (Mengin)	1224
The Ligation of Silver-Copper. (Matthey)	889
<i>Alterations to Bye-Laws.</i>	692
Alum, Concentration of the Mother-Liquors in the Manufacture of. (Wiernik)	731
Alumina, Basic Sulphate of. (Ferguson)	635
Manufacture of Pure, and Bye-Products. (P) Peniakoff	947
Manufacture of Salts or Compounds of. (P) Kessler	38
<i>Aluminium, Action of Iron Sulphide on.</i>	1063
Action of, on Cast Iron	737
Action of, on Sulphates and Chlorides. (Rossel and Frank)	515
Alloy. (P) Roman	956
Alloys, Manufacture and Industrial Value of. (Daggar)	4
And Aluminous Compounds, Manufacture of. (P) Peniakoff	947
Application of. (P) Taylor	42
Bronze "Doctor" for Printing Machines	388
Coating Paper with. (P) Ibbotson	170
Decomposition of Sodium Peroxide by. (Rossel and Frank)	516
Electrometallurgy of	43
Employment of, in Refining Metals	955
Foil as a Beer-Clarifying Agent. (Windisch)	969
Flux for Soldering. (P) Thompson, From Nicolai	890
Impurities of Commercial. (Moissan)	1190
Influence of, on the Carbon in Ferro-Carbon Alloys. (Hogge) (illus.)	955
Manufacture of Salts or Compounds of. (P) Kessler	38
Method for Plating. (Göttig)	1200
Modern Processes for the Manufacture of. (Bucherer)	42
Or its Diluent Alloys, Coating Metals with. (P) Broadwell	815
Preparation of Crystalline Carbide of. (Moissan)	1199
Process for Soldering. (P) Singer, Donat, and Kirchheim	645

<i>Aluminium—cont.</i>	
Qualitative Detection of. (Neumann)	849
Solder for. (P) Nicod	645
Sulphate, Manufacture of. (Jursch)	516
Sulphide, Formation of. (Gorny)	742
Sulphide, Manufacture of. (P) Vautin	178
The Reduction of, as a Scientific Problem. (Bucherer)	522
U.S. Report on the Manufacture of. (T.R.) (illus.)	79
Use of, in Lithography. (T.R.)	201
<i>Amalgam, Influence of Fractional Electricity on Formation of an. (Stuats)</i>	43
Amalgamating Apparatus. (P) Green	102
America, Manufacture of Sulphuric Acid in. (Lange) (illus.)	881
Preparation of Carbon Black from Natural Gas in. (Cibot) (illus.)	128
The Coke Problem in. (T.R.)	859
Water-Gas in. (Bredel)	715
<i>Aminoalkylalcoholic Acid, Manufacture of. (P) Abel and Murray. From Kuehler and Boff</i>	69
Bases, Manufacture of New. (P) Koroff	622
Cresolsulpho Acid, Production of. (P) Lake. From Oehler	723
Naphtholsulpho Acid, Manufacture of a New. (P) Newton. From The Farb. vorm. Bayer and Co.	943
Naphtholsulpho Acid, Manufacture of 2:7. (P) Abel. From The Acten Gesellschaft fur Anilin Fab.	876
Naphtholsulphonic Acid, Manufacture of a New. (P) Abel. From The Acten Gesellschaft fur Anilin Fab.	32
Naphthol Sulpho Acid, Production of. (P) Pitt. From Cassella and Co.	244
Naphthol-Sulpho Acids, Production of. (P) Newton. From The Farb. vorm. F. Bayer and Co.	800
Phenol Acid, Production of. (P) Lake. From Oehler	723
Phenols, Naphthalens of Substituted. (Ulzer and Haller)	730
Sulpho Acid, Production of a New. (P) Johnson. From The Badische Anilin und Soda Fab.	724
<i>Amine Bases, Recovery of Iron from Residue of the Manufacture of. (P) Bromhead. From Landshoff and Meyer.</i>	42
<i>Ammonia, Action of Gaseous, on Magenta. (Prud'homme and Rabaut)</i>	382
Amount of Sulphate of, produced in the United Kingdom. And Cyanides direct from the Air, Obtainment of. (P) Young	729, 1196
And Magenta Colouring Matters, Compounds formed by. (Prud'homme and Rabaut)	382
Apparatus, Construction of. (P) Davis	948
Apparatus for Obtaining. (P) Lake. From Sternberg	887
Decomposition of Chlorides and Iodides of Amines by. (Prud'homme and Rabaut)	382
Defecation of Beetroot Juice with. (Hanus)	263
Estimation of, by means of the Colorimeter. (Hosva)	842
Estimation of, in Liquids containing Sulphur or Cyanogen. (Henry)	761
Explosives from Nitrate of, and Resins. (P) Abel. From König	543
From Fuel, Apparatus for Obtaining. (P) Mond (illus.)	938
-Gas, Action of, on Peroxides. (Michel and Graudmoulin)	37
Influence of Acid Molybdate of, on Rotatory Power of Rhamnose. (Gernez)	1226
Manufacture of Carbonate of. (P) Raspe	395
Method and Apparatus for Producing. (P) Boul. From Cowen (illus.)	119
Production of, and Monocyclic Phosphate. (P) Hurter and Omholt	409
Soda Process, The Commercial Production of Chlorine by the. (Bide) (illus.)	509
Sodium Hydroxide and Chlorine, Process and Apparatus for Manufacturing. (P) Kellner	152
Washers for Separating, from Gas. (P) Cripps (illus.)	379
<i>Ammoniacal Liquor, Apparatus for Distillation of. (P) Pettigrew</i>	734
Liquor, Apparatus for the Distillation of. (P) Spence and Gilchrist	394
Liquor, Valves for. (P) Cripps	508
<i>Ammonio-Cupric Oxide, Stains on Woollen Cloth caused by. (Walter)</i>	946
<i>Ammonium Carbonate, German Trade in. (T.R.)</i>	1111
Formate, Production of, and Hydrocyanic Acid therefrom. (P) De Lambilly	58
Nitrate, Preparation of. (Benker)	515
<i>Ammunition in India. (T.R.)</i>	1115
<i>Amylaceous Materials, Deodorising or Bleaching. (P) Abel. From König</i>	824
Amylodextrin. (Linfner and Dull)	53
Aulene, Isomers and Analogues of. (Vis)	273
(Ortho - E-thoxy - Ana - Mono - Benzoylamido - Quinoline). (Jahn)	1138
<i>Analysis, Employment of "Micro-Chemical" Reagents in. (Leuz)</i>	765
Quantitative Electrolytic. (Classen)	1223
Quantitative Electrolytic. (Rudolf)	1223
Analytical Association in Germany, Proposed. (T.R.)	512
Chemistry and Apparatus. (Class XXIII.) 61, 174, 277, 543, 661, 760, 837, 904, 975, 1090, 1220	418
<i>Andropogon Schoenanthus, Geraniol from Oil of. (Barlier and Bouveault)</i>	1086
Anethol, Transference of Essence of Tarragon into. (Grimaux)	658
Anhydro-ortho-sulphamine Benzoic Acid, Manufacture of. (P) Lang	836

For Extracting Fat and Glue. (P. Machalski) .....	648
For Extracting Gold and Silver from Ores. (P. Trug) .....	527
For Extracting Oil by Volatile Solvents. (P. MacIwaine and Hardingham) .....	745
For Extracting Oil, &c. from Fibrous Materials. (P. Forles) .....	261
For Extracting Substances by Volatile Solvents. (P. Meikle) .....	622
For Extracting Suint. (P. Richard-Lagerie) .....	962
For Extraction. (Etraix) (illus.) .....	839
For Filtering and Purifying Water. (P. Winkler) .....	377
For Filtering Liquids, or Separating Liquids from Solids. (P. Drummond) .....	377
For Fining Beers and Filling Casks. (P. Crossman) .....	1082
For Fractional Distillation. (Otto) (illus.) .....	837

## Apparatus—cont.

For Fractional Distillation. (Varenne) (illus.)	761
For Fractional Distillation. (Volney) (illus.)	652
For Galvanising Sheet Metal. (P) Laques	178
For Gas Analysis. (Fischer) (illus.)	42
For Gas-making. (P) Hartley	1050
For Gassing Yarn and other Threads. (P) Clouzel	880
For Glazing and Enamelling Heavy Earthenware. (P) Twyford	396
For Generating Gaseous Fuel. (P) Thwait and Threlfall (illus.)	717
For Hardening and Tempering Steel. (P) Fichtax and Beardmore	1067
For Heating Air and Fluids. (P) Fudickel	1181
For Heating and Condensing. (P) Hennebert	713
For Heating, Evaporating, and Condensing. (P) Normandy	29
For Heating or Evaporating Liquids. (P) Morsen	622
For Lifting Blasting-Charges. (P) Roth	690
For Lighting and Heating by Petroleum. (P) De Pass, From Leeumont	141
For Making Bleaching-Powder. (P) Milnes	1039
For Making Vinegar and Maturing Spirits. (P) Lecker	635
For Manufacture and Purification of Iron. (P) Clapp and Williams	1261
For Manufacture of Alkali. (P) Hargreaves and Bird	250
For Manufacture of Alkaline Metals by Electrolysis. (Borchers) (illus.)	159
For Manufacture of Artificial Whalebone. (P) Levy, Rustin, and Boyer	1074
For Manufacture of Beer. (P) Billings	896
For Manufacturing Caustic Soda. (P) Crane (illus.)	636
For Manufacture of Coke, Coal-Gas, &c. (P) Dykowitz	626
For Manufacture of Gas. (P) Dismore	934
For Manufacture of Gas and Bye-Products. (P) Young	1035
For Manufacture of Margarine and Alimentary Fat. (P) Cordewener and de Kunwald	270
For Manufacture of Metallic Pigments or Compounds. (P) Charlier	532
For Manufacture of Paper Pulp. (P) Caldwell	1085
For Manufacture of Pottery. (P) Shack	1062
For Manufacture of Soap Tablets. (P) Finlay	905
For Manufacture of Spirits. (P) Murphy	751
For Manufacture of Sugar. (P) Johnson, From Pellegrini (illus.)	1056
For Manufacture of Sulphocyanides. (P) Brock and others	1195
For Manufacture of Water-Gas. (P) Glasgow	934
For Manufacture of Water-Gas. (P) Paisley	212
For Manufacture of Water-Gas. (P) Westcott (illus.)	1051
For Manufacturing White Sugar from Molasses. (P) Hubner	824
For Measuring Pressure of Gas in Gurs. (P) Castenholz	929
For Mixing and Regulating Paper Stuff. (P) Borland	754
For Mixing Gas and Air. (P) Axdorfer and Sass	1050
For Notifying Presence of Gases in Air. (P) Hardy	1091
For Obtaining Ammonia and Ammonia Salts. (P) Lake, From Sternberg	887
For Obtaining Carbonic Acid. (P) Muller (illus.)	636
For Obtaining Constant Pressure during Estimation of Freezing Point of Oils. (Gantter) (illus.)	1090
For Obtaining Cyanogen, Cyanides, &c. (P) Aiken (illus.)	517
For Obtaining Distilled and Sterilised Water. (P) Nagel	169
For Obtaining Gas from Coal-Tar. (P) Smith	626
For Obtaining Gases, Ammonia and Tar from Fuel. (P) Mond (illus.)	968
For Obtaining Glycerin from Spent Lyes. (P) Ruymbeke and Jobbins	1070
For Obtaining more perfect Combustion of Fuel. (P) Taylor	139
For Oxidising Indigo Blues. (P) Grime	728
For Pasteurising Beer. (Windeck)	267
For Pasteurising Milk, &c. (P) Paaseh	1215
For Pickling Metal Articles. (P) Cowper-Coles	889
For Powdering Roasted Cements. (P) Bollee and Benard	1198
For Precipitating Gold and Silver from Cyanide Solutions. (P) Bell and Carter	816
For Preparation of Malt. (P) Schmiedecke and Gade	827
For Producing and Consuming Gas. (P) Hall	528
For Producing an Improved Paper or Fabric. (P) Wheeler	639
For Producing Artificial Silk. (P) Lehner	1192
For Producing Carbonic Acid Gas. (P) Lane and Fulman	810
For Producing Chlorate of Potash by Electrolysis. (P) Hunter	810
For Producing Pure Castings. (P) Müller	800
For Production of Cranides. (P) Gordon	886
For Production of Metallic Pigments. (P) Charlier	407
For Production of Mineral-Oil Gas and Water-Gas. (P) Young (illus.)	934
For Production of Oxygen from Air. (P) Bria's Oxygen Co. and Murray	856
For Production of Ozone from Phosphorus. (P) Kattenhof	414
For Production of Sulphuretted Hydrogen. (Kuster) (illus.)	278
For Pumping and Absorbing Chlorine Gas. (P) Worsley, Windus, and Bracey	810
For Purification of Gas. (P) Fleischhauer and Bernstein (illus.)	718
For Purifying Feed-Water. (P) Wotherspoon and Davie	505
For Purifying Liquids. (P) Wagner and Marr	751
For Purifying Sewage and Waste Liquids. (P) Adeney and Parry	831

## Apparatus—cont.

For Purifying Water. (P) Maché	841
For Purifying Water. (P) Walker	163
For Purifying Water. (P) Webster	163
For Raising Liquids. (P) Moore	163
For Raising Liquids and Sea Liquids. (P) Taylor	24
For Raising or Aerating Water or other Liquids. (P) Store	964
For Raising or Pumping Liquids. (P) Kestner	625
For Rapid Determination of Carbonic Acids. (P) Pouché (illus.)	241
For Refining Metal by Electrolysis. (P) Hesse and Symon	544
For Refrigerating. (Linder) (illus.)	1068
For Regulating Temp. of Fermenting Liquids. (P) Collins	752
For Regulating Temp. of Fluids. (P) Royle	87
For Removing Fibrous Matter from Cotton-Seed. (P) Thompson, From Stead	1179
For Removing Impurities from Water. (P) Shaddock	820
For Scouring and Degreasing Wool. (P) Boys, From Mahud	23
For Scouring and Washing Fabrics. (P) McNaught	880
For Scouring, Degreasing, and Cleansing Wool. (P) Turney	805
For Scouring Wool. (P) Turney	634
For Separating and Purifying Minerals, &c. (P) Beyer (illus.)	944
For Separating Oil from Feed-water. (P) McDougall	623
For Separating Substances. (P) Anderson, jun.	29
For Separation of Metals, &c. (P) May	871
For Shaking Bottles. (Maill) (illus.)	740
For Sizing Yarn. (P) Maaz	1220
For Smelting and Refining Copper. (P) Vienna	880
For Softening and Purifying Water. (P) Doulton and Manger	644
For Softening and Purifying Water. (P) Smith	832
For Softening Water. (P) Gittins	538
For Sterilising. (P) Hussener	271
For Sterilising Beers, Beverages, &c. (P) May and Newlands	1215
For Sterilising or Disinfecting Liquids. (P) Ottmann and Herbst	771
For Sterilising Water. (P) Yagin	137
For Straining Pulp, &c. (P) Reimcke	416
For Superheating Steam. (P) Musgrave and Dixon	713
For Supplying Carbonic Acid under Pressure. (P) Browne, From Beck	1048
For Supplying Liquid Fuel to Furnaces. (P) Etchells	788
For Testing Gas Cylinders. (P) The Scotch and Irish Oxygen Co. and H. Brier (illus.)	1094
For Testing Paper. (P) Woolley (illus.)	789
For the Continuous Production of Nitric Acid. (Prestice) (illus.)	1222
For the Distillation of Ammoniacal Liquor. (P) Spence and Gilchrist	323
For the Preparation of Malt. (P) Genze	394
For Treating Fibres. (P) Brintons, Lim, and Hansen	412
For Treating Fibres by Liquids. (P) Miller	885
For Treating Powdered Materials. (P) Petwiler	884
For Treating Refuse. (P) Smithson	1181
For Treating Salts Electrolytically. (P) Stormer	271
For Treating Soap. (P) Candy	1067
For Treating Substances containing Fats and Oils. (P) Robbins	1215
For Treating Textiles. (P) Gimes	1070
For Treating Textiles. (P) Jackson and Hunt	248
For Treating Yarns. (P) Jacob	944
For Treatment of Wort, &c. (P) De Geyer (illus.)	596
For using Producer-Gas for Cementing Limestone. (P) Boulton, From Hatch (illus.)	637
For Utilising Lyes of Sulphite Cellulose. (P) Mitscherlich	834
For Valuation of Manganese Dioxide. (Ullmann) (illus.)	879
For Vaporising and Burning Mineral Oil. (P) Grosche	139
For Vaporising Oil. (P) Laird	873
For Washing, Bleaching, Dyeing, and Mordanting. (P) Owens and Whiteley	390
For Washing Fibres. (P) Lazarus and Jefferson	945
For Washing Filtering Media. (P) Thompson, From Arnold (illus.)	25
For Washing Gas. (P) Marshall (illus.)	716
For Washing Photographic Plates and Prints. (P) Thompson	550
For Washing Wool or other Fibres. (P) Dawson	509
For Weighing out Liquids. (Schweitzer and Lunawitz) (illus.)	838
For Working Ores. (P) Allison, From Storer, Martin, and Eaton	816
Hydrostatic, for Treating Liquids and Solutions. (P) Spence	613
Rotary, for Washing and Dyeing. (P) Crabtree	884
Safety Appliances for Use with Electrical Decomposing. (P) Richardson	958
Some Laboratory. (Bidet) (illus.)	621
Apple, Development and Ripening of the Cider. (Lindet)	54
Formation of Cane Sugar during Ripening of the. (Lindet)	750
Study of the Variety of, used for Cider-making. (Truelle)	266
Apples, Preparation of Alcohol from. (Vivian and Dupont)	902
Appliance for Breaking down Crust in Gas-Producers. (P) Hall	627
Aqua Regia, Influence of, on Precipitation of Barium as Sulphate. (Browning)	176

	PAGE
Argentina, New Customs Law of. (T.R.)	182
The Vanadiferous Lignite found in. (Kyle)	738
Arenatics, Production of Substances for Manufacture of. (P)	
Titanium	903
Arsenic, Detection and Separation of. (Gleichen and Hodge)	979
Elimination and Recovery of, from Copper Precipitates. (P) North	1291
In Copper, Modification of Ferric Chloride Process for Estimation of. (Platten)	324
In Sulphides, Determination of. (Jannasch) (illus.)	905
Artichoke, The Carbohydrates of the Jerusalem. (Tauret)	52
Artillery, German Trade in. (T.R.)	1113
Asbestos Industry of Canada, The. (T.R.)	993
Mining in Canada. (T.R.)	674
Baking, Improved Compound. (P) Field	788
Use of, for Filtration of Sugar, Juices, and Syrups. (Maurer)	264
Asphaltic Composition, Production of. (P) Sherer	618
Asphalt Paving, U.S.A. Report on.	726
Asphaltum, Notes on. (Niederlander)	263
Or Pitch, Artificial, and Production thereof. (P) Haddan. From Anderson, Shorler, Kochler, and Dorer.	729
Aspidium Filix, Extract of the Root of. (Ehrenberg)	758
Assam, India-Rubber Production in. (T.R.)	433
Atmosphere, Attempts to Estimate Sulphur Compounds in the. (Oates)	1222
Effect of the, upon Glass. (Foerst)	518
Atropine Alkaloids, The. (Hesse)	416
Auditors, Appointment of.	700
Aver Incandescent Mantle, Is it Poisonous? (Grichant)	1050
Auzsburg, Treatment of Municipal Refuse at.	412
Auramine, Manufacture of. (P) Johnson. From The Badische Anilin und Soda Fab.	247
Auramines, The. (Stock)	244
Aurin. (Herzig and Smoluchowski)	798
Austen Process for Treatment of Pyritic Minerals by Fusion	812
Australia, A Discovery of Coal in. (T.R.)	78
Austria-Hungary, New Patent Law in. (T.R.)	71
Portland Cement Industry in. (T.R.)	1108
The Mineral Production of. (T.R.)	994
Average Prices of General Commodities in England, Course of. (Sauerbeck) (illus.)	Facing p. 672
Azo-Coulour Resists on Steam-printed Indigo. (Schlieper and Bloch and Schwartz)	1193

## B

Bacteria of Cholera and Typhoid, Action of Peat Dust on. (Frankel and Kilpstein)	538
of Hides, Action of Salt on. (Haendlein)	49
Removal of Pathogenic from Drinking-Water. (Fuller)	830
Baking-Powder. (P) Brothers	752
Powder, Means of using. (P) Daim, Brown and Polson	1083
Baku, The Petroleum Industry in, 1893.	875
Balances, Improvements in. (P) Thomson	66
Balanta Production in Surinam. (T.R.)	430
Banana-mel, Production of, in Surinam. (T.R.)	430
Bank Notes, Manufacture of Paper for. (P) Buttner and Will	539
Barium and Calcium, Separation of. (Browning)	282
Estimation of, in Presence of Calcium and Magnesium. (Mar)	282
Influence of Free Nitric Acid and Aqua Regia on Precipitation of, as Sulphate. (Browning)	176
Peroxide, Action of Ammonia-Gas on. (Michel and Grandmaison)	37
Salts, Manufacture of.	392
Barley, Formation of Cane-Sugar during Germination of. (Lander)	750
Influence of Iron on the Vegetation of. (Pott)	632
Production of Saccharose during Germination of. (Lander)	265
Taking Specific Gravity of, by Means of Volumetric Barley-Balances	1078
Bartlett's z-Lead Process, Report on The. (Hawker)	41
Bases, Action of, on Glucoses. (Jessen)	264
In certain Metallic Salts, Volumetric Estimation of. (English)	515
Manufacture of New Amides. (P) Korell	632
Of Salts and Compounds thereof, Electrical Separation of, from Saline Solutions. (Vautin)	256
Titration of Organic, with Methyl Orange. (Lunge)	607
Basic Compounds from Pyrazine, Production of. (P) Newton. From The Farb, vorm. Bayer and Co.	510
Steel Production in 1893. (T.R.)	292
Bath, a New Form of Air. (Sauer) (illus.)	692
Baths for Hardening and Toughening Iron and Steel. (P) Bates	645
Battery, Darrius' Theory of the Lead Secondary. (Schoop)	1293
Batteries, Various:—	
Accumulator, A New. (Leuz)	158
Accumulators, Electric. (P) Ellermann	161

## Batteries—cont.

Accumulators, Electric. (P) Schroeder	800
Dry. (P) Johnson	404
Electrical. (P) Feeny. From Hubers and Mohrdeck	1068
Galvanic. (P) Buell	1068
Galvanic. (P) Boult. From Cudell	647
Galvanic. (P) Schroeder	160, 169, 528
Portable Primary. (P) Morison	1067
Primary Galvanic, and Liquids thereof. (P) Longsdorf. From Hewitt	818
Primary Voltaic. (P) Walker, jun., and Wilkins	529
Primary Voltaic. (P) Walker, jun., and others	1206
Secondary. (P) Doubleday. From Susmann	528
Secondary. (P) Petschel	256
Secondary. (P) Peyrussou	646
Secondary. (P) Schoop	646
Secondary Electric. (P) The Lithanode and General Electric Co. and Niblett	818
Secondary Voltaic. (P) Clulbe and Southey	45
Storage. (P) Johnson. From La Soc. L'Accumulateur Fulmen	819
Storage. (P) Kordon	1206
Storage. (P) Thompson. From Hartung	256
Storage. (P) Usher	162, 162
Storage. (P) Young. From The Hess Storage Battery Co.	1206
Thermo-Electric, and Apparatus for Manufacture thereof. (P) Dion	890
Voltaic. (P) Gregg	1205
Battery Cells, Plates, Elements, Solutions, &c.:—	
Active Material for Accumulators. (P) Mills. From Barbier	1206
Carbon for Electric Batteries. (P) Lake. From Girard and Street	647
Carbon for Electrical Purposes. (P) Acheson	1207
Carbon for Electrical Purposes. (P) Newirth	1206
Carbon for Electrodes. (P) Casner	1067
Cells and Diaphragms, Electrolytic. (P) Hargreaves and Bird	255
Cells, Electrolytic, and Diaphragms thereof. (P) Waite	959
Cells for Electric Batteries. (P) Emery	404
Cells for Electrolytic Apparatus. (P) Hurter, Auer, and Muspratt	958
Diaphragms for Electrolytic Purposes. (P) Kiliani and others	1068
Electrode Plates for Accumulators. (P) Lehmann	1206
Electrodes and Cells for Accumulators. (P) Wheeler	647
Electrodes, Carbon. (P) Barnett	44
Electrodes, Carbon. (P) Livinge	161, 161
Electrodes, Electro-Positive Galvanic. (P) Schroeder	257
Electrodes for Accumulators, Manufacture of. (P) Pollak	44
Electrodes, Platinised. (P) Barnett	44
Electrolytes for Primary Batteries. (P) Longsdorf. From Hewitt	890
Elements for Secondary Batteries. (P) The Lithanode and General Electric Co. and Niblett	256
Elements for Voltaic Batteries. (P) Fitzgerald	743
Elements or Plates for Secondary Batteries. (P) Picard and Thame	256
Plate for Electrical Accumulator. (P) Mills. From Barbier	1206
Plates for Accumulators. (P) Gulcher	741
Plates for Accumulators. (P) Rousseau	744
Plates for Secondary Batteries. (P) Blot	819
Plates for Secondary Batteries. (P) Hough	44
Plates for Secondary Batteries. (P) The Lithanode and General Electric Co. and Niblett	744
Plates for Secondary Batteries. (P) Thompson. From La Soc. Electric Phœbus	161
Plates of Secondary Voltaic Batteries, Treatment of. (P) Epstein	743
Plates or Elements for Secondary Batteries. (P) Hough and March	161
Beakers for Dyeing Tests, Hard Glass. (Lepetit)	978
Bean, The Proteids of the Kidney. (Osborne)	828
Beer, Alleged Disappearance of Added Salicylic Acid and Saccharine from. (Wauters)	969
Apparatus for Pasteurising. (Windeck)	267
Apparatus for Manufacture of. (P) Billings	896
Apparatus for Sterilising. (P) May and Newlands	751
Clarification of. (P) Lake. From Muller	269
Composition for Preserving. (P) Pickles	1083
Effect of Albuminoids in Manufacture of. (Wahl and Nilson)	896
Effect of Alkaline Chlorides on Flavour of	1080
Effect of the Saline Constituents of Water on the Character of. (Readman)	367
Evolution of Carbon Dioxide, and Hydrogen Sulphide in Boiling. (Elion)	267
"Gluten Particles" occurring in. (Will)	967
Influence of Hop-Tannin on. (Hayduck and Goldiner)	967
Influence of Mashing Process on Attenuation of. (Windisch)	967
Manufacture of. (P) Lake. From Tedesco	896
Manufacture of. (P) Pennington	656
Manufacture of. (P) Pkhardt	535
Method and Apparatus for Collecting Carbonic Acid during Fermentation of. (P) Michel and Frank	655
Presence of Boric Acid in. (Brand)	34
Production of Coconut- and Rice. (Calmette)	268
Regulations Affecting the Adulteration of, in Belgium. (T.R.)	290

Printing. (P) Lang.	150
Printing Machinery. (P) MacPhail	1194
Prints, Production of Fast Reds in. (Dopierre)	1194
California, Discovery of Native Antimony in. (T.R.)	78
Calomet, Manufacture of, in Japan. (Divers) (illus.)	108
Camphele in Spike Oil, Presence of. (Bouchardat)	658
Occurrence of, in Etheral Oils. (Bertram and Walbaum)	756
Presence of, in Essence of Lavender. (Bouchardat)	756
Campholene. (Guerbet)	628
Camphor as a Reagent for Sugar. (Neitzel)	843
Compositions of, with other Substances. (P) Verdun	57
Canada and the American Drug Trade. (T.R.)	995
Chronic Iron in Quebec. (T.R.)	911
Mineral Production of, for 1893. (T.R.)	555
Phosphate and Asbestos Mining in. (T.R.)	674
Tariff Changes in. (T.R.)	672, 769, 846
The Asbestos Industry of. (T.R.)	993
Canaisiere. (Kapff)	946
As a Substitute for Bark in Tanning	650, 894
Canal, the Manchester Ship	11
Cancer, Preparation for Treatment of. (P) Watson	417
Candl's, Rules for the Preparation of Standard Sperm	65
Sulphur, and their Holders. (P) Kingzett	657
Cannabinden. (Kobert)	902
Cannabis Sativa, Occurrence of Trigonellin in Seeds of. (Schulze and Frankfurt)	757
Cannels, General Characters of Boghead. (Bertrand and Renault)	241
Canvass, Rendering, Sensitive to Light. (P) Junk	173
Caoutchouc in Bolivia, Supplies of. (T.R.)	673
Manufacture of Artificial. (P) St. George	48
Membrane, Diffusibility of certain Gases through. (Reyher)	181
Carouel, The Properties of. (Sabanejell and Antouchevitch)	1076
Carbamides, Solutions of Sweet, in Oils, Fats, &c. (P) Sommer	1071
Carbides, The Production of Various. (Muhlhauser)	34
Carbohydrates, Colorimetric Methods of Estimating. (Reitzel)	985
Of the Fruit of the Kentucky Coffee-Nut Tree. (Stone and West)	536
Of the Jerusalem Artichoke. (Tanret)	52
Of Yeast, The. (Salskowski)	411
Pre-existing in Malt. (Jalowetz)	967
Quantitative Colorimetric Estimation of. (Neitzel)	285
Quantitative Estimation of. (Schulze)	985
Carbolic Acid, German Trade in. (T.R.)	1214
Carbon and Iron, Transformations of, in Tempering. (Charpy)	1066
Bisulphide, Manufacture and Refining of, at Zalata. (Farbaky) (illus.)	508
Black, Note on Cabot's Paper on Preparation of, from Natural Gas. (Irvine)	131
Blacks, Preparation of, from Natural Gas in America. (Cabot) (illus.)	128
Dioxide and Nitrogen in Air, Minimum Proportion of, Extinctive of Flames. (Clowes and Feilmann)	1155
Dioxide, Apparatus for Estimating. (Christomanos) (illus.)	1221
Dioxide, Evolution of, in Boiling Beer, Wort and Hops. (Elion)	267
Dioxide, Influence of, on the Growth and Life of Fermentation Organisms.	266
For Electrical Purposes, Manufacture of. (P) Lake, From Girard and Street	647
For Electrical Purposes, Manufacture of. (P) Niewerth	1206
In Ferro-Carbon Alloys, Influence of Aluminium upon (Hogg) (illus.)	955
In Iron and Steel, Determination of. (Hempel) (illus.)	421
In Iron, Examination of Methods for Estimation of. (Ledeber)	281
In Iron, Reliability of Principal Methods for Determining Total. (Gottig)	421
In Iron, Various Methods of Estimating. (Gottig)	1096
In Steel, Determination of. (Koch) (illus.)	979
In Steel, The Conditions in which it Exists. (Arnold and Read)	740
Monoxide and Olefines, Distinction between	841
Testing, Colour Gauzes for. (McMillan)	978
Tetrachloride, Production of. (P) Muller and Dubois	972
Carbonate of Ammonia, Manufacture of. (P) Raspe	394
Carbonates, Extraction of Carbonic Acid from Mineral. (P) Van Berkel	38
Manufacture of Alkaline. (P) Reich	1059
Carbonic Acid and Bye-Products, Manufacture of. (P) Enequist	948
Acid, Apparatus for Obtaining. (P) Muller (illus.)	636
Acid, Estimation of. (Wolkowicz)	904
Acid, Extraction of, from Mineral Carbonates. (P) Van Berkel	38
Acid Gas, Method and Apparatus for Producing. (P) Lane and Pullman	810
Acid, Method and Apparatus for Absorbing. (P) Muller	852
Acid, Method and Apparatus for Collecting, during Fermentation. (P) Michel and Frank	635

Caucasus, Petroleum Discoveries in the. (T.R.)	779	Exports of to British Colonies in 1893. (T.R.)	851
Petroleum Supply of the. (T.R.)	1231	Chemistry of Foods, Sanitary Chemistry, and Disinfectants. (Class XVIII.)	54, 168, 209, 412, 596, 656, 752, 827, 897, 939, 1082, 1215
The Manganese Trade of the. (T.R.)	558	Of Oil-Painting, Importance of Study of. (Petruschewsky)	252
Cells for Batteries. <i>See under Batteries</i> .		Recent Developments in Pharmaceutical. (Erdmann)	549
Manufacture of Porous. (Titaner)	888	Chili, Exemption from Duty of Potassium Cyanide in. (T.R.)	74
Cellulose, Crystallisation of, and Chemical Composition of the Cellular Membrane. (Gibson)	1196	Chimneys and Shafts, Construction of, and Bricks therefor. (P) Incham	623
Derivatives, Commercial. (Beadle)	901	China, Alkali Lands in North. (T.R.)	119
Manufacture of. (P) Kellner	115, 539	And Earthenware, Manufacture, Report of Committee of Enquiry on. (T.R.)	75
Manufacture of Straw. (Beveridge)	101, 213	Clay, Method and Apparatus for Refining. (P) Nicholls.	251
Nitrating. (P) Selphuang.	1220	Connecting Metal to. (P) Drayson.	811
Pulp, Manufacture of. (P) Johnson, From Sobogo	1216	Hermetically Joining the Surfaces of. (P) Doulton and Slater	637
Sulphuric Acid, and Products of its Hydrolysis. (Stern)	1230	Mosaic, Production of Watter. (P) Bale	519
Utilising Lyes of Sulphite. (P) Mitscherlich	834	Opium Adulteration in. (T.R.)	779
Celluloses of the Gramineae. (Smith)	537	Chloralic Acid. (Hanriot and Richet)	755
Cement, Adulteration or Improvement of. (T.R.)	1236	Chloralose. (Hanriot and Richet)	755, 755
Apparatus for Crushing. (P) Morel and Heimpel	623	Chloride of Lime. <i>See under Lime and Bleaching-Powder</i> .	
Chemical and Physical Examination of Portland. (Stillman)	278, 637	Chlorides, Action of, on Nitrosodimethylaniline. (Ehrlich and Cohn)	39
Composition and Treatment of Substances for Use as. (P) Walters	197	Action of Aluminium on. (R. v. v. and Frank)	515
Composition of Materials for. (P) Edwards, From Overton	737	And Mixtures thereof, Electrolysis of. (P) Lyte	404
Effect of Addition of Gypsum to Portland. (Schott)	251	Apparatus for Electrolysis of. (P) Harzeaves and Bird	958
Experiments on Slag. (Matton)	736	Effect of Alkaline, on Flavour of Beer	1089
For Porcelain, Transparent. (Deutsch)	888	Electrolysis of. (P) Harzeaves and Bird	886
From Alkali-Waste, Manufacture of. (P) Rigby, Neill, and Carr	918	Electrolysis of Alkaline. (Ost)	493
Kilns. (P) De Pass, From Lavocat and Candlot	1062	Electrolytical Decomposition of, and Apparatus therefor. (P) Lyte	958
Manufacture and Treatment of Fireproof Plastic Material for. (P) Stone	811	Chlorine and Bromine, Analytical Separation of. (Engel)	1094
Manufacture of. (P) Gui	638	And Bye-Products, Obtainment of. (P) Penikoff.	947
Manufacture of. (P) Webster	254	And Caustic Soda, Production of, by Electrolysis of Salt. (P) Drake	719
Manufacture of. (P) Kilpatrick	158	And Lime, The Interaction of. (Veley)	254
Manufacture of, from Alkali Waste. (P) Rigby, Neill, and Carr	638	And Refined Lead, Production of. (P) Lyte (illus.)	644
Manufacture of Hydraulic. (P) Stein.	529, 1062	And Soda, Apparatus for Electrolytically Producing. (P) Lake, From The Union Chemical Co.	257
Manufacture of Portland, Utilising Waste Carbonate of Lime. (P) Hill	255	Detection of Traces of. (Villiers and Fayolle)	1092
Manufacture of Pulverised Materials for. (P) Patrick	1018	Gas, Method and Apparatus for Pumping and Absorbing. (P) Worsley, Windus, and Incey	810
Mortar, Manufacture of. (P) Williams	1062	In Fats, Estimation of. (Benedikt and Zikes)	984
Portland, Industry in Austria-Hungary. (T.R.)	1198	Liberation of, during Heating of Mixture of Potassium Chlorate and Manganese Peroxide. (McLeod)	272
Quick Setting. (Geyer)	949	Liquid. (Fribourg)	151
Testing Hydraulic. (Prüssing)	949	Manufacture of. (P) Brand.	635
The Characteristics of Portland. (Fresenius)	252	Manufacture of. (P) Gaskell, Jun., and Cary	1196
The Composition of Portland. (Kosmann)	396	Normal, in Spring Waters. (Haines)	828
The Testing of Portland (Giron)	39	Process and Apparatus for Manufacture of. (P) Kellner.	152
Trade of Germany, The. (T.R.)	1237	The Commercial Production of, by the Ammonia-Soda Process. (Bale) (illus.)	206
Use of "Albano" as a. (P) Renison	648	Chloroform, Examination of, for Phosgene	1099
Utilising Precipitated Sewage for Manufacture of. (P) Bruch)	1198	Oxidation of, by Chromic Acid. (Erdmann) (illus.)	65
Cements. (Class IX.)	39, 154, 251, 396, 519, 637, 736, 811, 888, 949, 1062, 1198	Cholesterol, Separation of, from Wool Fats. (P) Krause and Mayer	162
And Cement Work. (P) Ropes and Sellars.	639	Choline and Betaine in Wormseed, Occurrence of. (Jahns)	57
For Leather Belting	164	Preparation of. (Schulze and Frankfurt)	54
The Testing of Hydraulic. (Stanger and Blount) (illus.)	155	Chromic Acid Discharge for Silk. (Kochlin)	737
Transforming Roasted, into Powder, and Apparatus therefor. (P) Belloc and Benard.	1198	Acid, Oxidation of Chloroform by. (Erdmann) (illus.)	67
Centrifugal Machines for Separating Liquids. (P) Ludloff (illus.)	240	Acid, Preparation of. (P) Placet and Bonnet.	57
Cereals, Manufacture of Dough from. (P) Gellinek	56	Chromium, Action of Iron Sulphide on.	1093
Manufacture of Prepared. (White)	635	Carbide, Production of. (Mullhauser)	35
Peptonised Extract of Malted and other. (P) Peptine		Extraction of, by Electrolysis, and Production of Chromium Alloys. (P) Placet and Bonnet.	643
Maltine, Lim., and Bartlett.	1083	In Chromium Steel and Chrome Iron Ore, Estimation of. (Spüller and Kalmann)	281
The Diastase of. (Ezgaroff)	1089	In Steel, Estimation of. (Schneid.)	546
Cetoses and Aldoses, Differentiation of. (Villiers and Fayolle)	1698	Lakes, Dyeing Wool with. (P) Hoffmann	881
Chalybeate Water, Apparatus for Producing Artificial. (P) March	529	Making Green Oxide of. (P) Socum and Wheeler.	1071
Chamber-Kilns, Improvements in. (P) Jung.	154	On the Mordanting of Wool with. (Lieschi and Hummel)	356
Champaecol. (Merek)	831	(Part III.) 222, (Part IV.) 356

various Matters and Dyes Various. <i>cont.</i>	
Sulpho Acids of Phenyl Sandoline, and Analogs and Homologues thereof. (P. Johnson. From The Badische Anilin und Soda Fabrik.)	519
Sulpho Acids. Production of. (P. Newton. From The Farb. vorm. Bayer and Co.)	578
Tannin Orange. (Schmidt)	1189
Trihydroxyphenylthale Monosulpho Acid. Production of. (P. Newton. From The Farb. vorm. Bayer and Co.)	1054
As Binding Material for Size. (P. Classen)	902
On a Method of Dyeing Leather with Basic. (H. G. and Procter)	895
Report of Committee on Action of Light. (P. Dyck. Hummel)	843
The Tinting of. (Dyck)	633
The Quinonoxanes in S. and. (Friedlemaier)	148
malin, The New Sodium Nitrate Deposits of. (T.R.)	1001
Castile Composition. (P. Odern)	1957
Position, Cause and Prevention of Spontaneous. (Hapke)	26
Chambers, Controlling Heating. (P. Land and Calkins)	997
Of Lamps. (H. Spontaneous. (Dyck)	670
Of Lamp Shades. Spontaneous. (Dyck)	670
Agency, Proceedings of Chambers of. (T.R.)	1231
Position for Coating. (P. M. and W. W.)	153
For Coating Iron and Steel. (P. Elliott)	992
For Coating Iron and Steel. (P. Walters)	993
For Incubators. (P. H. and P. H.)	793
For Moulds, Elastic. (P. H. and P. H.)	1211
For Preventing and Removing Boiler-Incrustation. (P. Borecki and K. H. and P. H.)	714
For Protecting Lead Surfaces. (P. H. and P. H.)	895
For Uses in. (P. H. and P. H.)	752
For Uses in. (P. H. and P. H.)	648
Improved Antifouling. (P. H. and P. H.)	1216
Positions for Preserving Beer and other Liquids. (P. H. and P. H.)	1083
Pickles. (P. H. and P. H.)	832
For Treatment of Sewage and Foul Waters. (P. H. and P. H.)	326
suitable for Paying. (P. H. and P. H.)	631
suitable, An Electric Insulating. (P. H. and P. H.)	807
For Production of Indigo upon the Fibre. (P. H. and P. H.)	656
For Purifying Sewage and Foul Liquids. (P. H. and P. H.)	260
For Seaming Textiles. (P. H. and P. H.)	661
For Use in the Manufacture of Matches. (P. H. and P. H.)	638
Production of an Asphaltic. (P. H. and P. H.)	759
ounds for Alimentary and Medicinal Purposes. Manufacture of. (P. H. and P. H.)	1082
For Manufacture of Ginger Beer and other Fermented Beverages. (P. H. and P. H.)	1209
For Removing Old Paint. (P. H. and P. H.)	1216
For Treating Sewage. (P. H. and P. H.)	532
For Waterproofing Leather. (P. H. and P. H.)	1216
For Use in Treating Sewage. (P. H. and P. H.)	158
Manufacture of Metallic. (P. H. and P. H.)	754
Manufacture of Oleum or Saponaceous, for Producing Medicinal Emulsions or Disinfectants. (P. H. and P. H.)	797
of Hydrogen Cyanide with the Alkaloids of the Sugars. (P. H. and P. H.)	745
of Iron with Fatty Acids. (P. H. and P. H.)	417
Of the Citral (Geraniol) Group. (P. H. and P. H.)	765
of the Sugars with Polyhydric Phenols. (P. H. and P. H.)	674
pendent General of. (P. H. and P. H.)	708
Concentrating Apparatus. (P. H. and P. H.)	661
Condenser, an Internally Cooled. (P. H. and P. H.)	626
Condensers, Gas. (P. H. and P. H.)	761
For Laboratories. (P. H. and P. H.)	930
Condensing Plates. (P. H. and P. H.)	569
Condensing House and Bradford. (P. H. and P. H.)	767
Condensing and Nitrogen. (P. H. and P. H.)	886
Condensing, Behavior of Woods of the, to Solutions of the Chlorides of Copper. (P. H. and P. H.)	835
Condensing and its Compounds. (P. H. and P. H.)	753
Condensing. (P. H. and P. H.)	1217
Condensing Alkaloids. (P. H. and P. H.)	71
Condensing and Reception. (P. H. and P. H.)	715
Condensing Apparatus. (P. H. and P. H.)	1081
Cop Bottoms, Paste or Size for. (P. H. and P. H.)	957
Copiba, Detection of Castor-Oil in Balm of. (P. H. and P. H.)	1222
Copper, Action of Copper Sulphate and Sulphuric Acid on Metallic. (P. H. and P. H.)	289
Analysis of American Redwood. (P. H. and P. H.)	886
And Lead, Separation of. (P. H. and P. H.)	1992
And Tin, Electrolytic Separation of. (P. H. and P. H.)	817
Behavior of Woods of the Conifer to Solutions of the Chlorides of. (P. H. and P. H.)	957
Compounds, Delicate Reaction for. (P. H. and P. H.)	240
Compounds, Electrolytic, in the Stillberg Lead Works. (P. H. and P. H.)	

	PAGE
Copper— <i>cont.</i>	
Estimation of, as Copper Sub-sulphide. (Wegscheider)	67
Experiments on Analysis of Pig. (De Benville)	667
From Chaldean and Egypt, Composition of Ancient. (Berthelot)	1198
Modification of Ferric Chloride Process for Estimation of Arsenic in. (Platten)	321
Occurrence of, in Extracts. (Holl)	902
On New Alloys of. (Von Knorre)	815
Ores of, Peta, the. (T.R.)	435
Phosphor. (McComb)	1139
Plate Ink, Manufacture of. (Villon)	721
Preparations, Recovery of Arsenic from. (P. North)	1291
Process and Apparatus for Smelting and Refining. (P. Vienna)	644
Production of Japanese. (Gowland) (illus.)	463
Recovery of, from Deacon Process Bricks. (P. Wyle and Williams)	1059
Silver Alloys, Liquefaction of. (Matthey)	889
Simple Method for Determining Foreign Metals in. (Hampel)	421
Sulphate, German Trade in. (T.R.)	1111
Sulphate, Manufacture of. (P. Strawson and Fream)	57
Sulphate, The Electrolysis of. (Chassy)	1204
Solutions, Behaviour of. (Jannasch and Lesnisky)	67
Volumetric Determination of. (Bornträger)	67
Corrections to be Applied in Titrating Liquids containing Suspended Matter. (Lenoble)	762
Corrosive Sublimates, Stability and Preservation of Dilute Solutions of. (Vignon)	171
Sublimates, Stability of Dilute Solutions of. (Vignon)	1087
Sublimates, Stability of Solution of, exposed to Air. (Tanret)	657
Corybulline. (Dobbie and Lauder)	1217
Corydalis. (Dobbie and Lauder)	1217
Corydalis Cava, Alkaloids in the Root of. (Freund and Josephi)	59
Cava, The Alkaloids of. (Dobbie and Lauder)	1217
Coto-bark, A New Derivative from. (Ciancin and Silber)	756
Cotton. (Class V.) 32, 145, 248, 384, 512, 632, 725, 802, 880, 944, 1056, 1192	
Cloths for Filtering Purposes, Treatment of. (P. Newton. From de Haen)	34
Cloths, Method for Bleaching. (P. Schott)	631
Dyeing with Benzidine Colours. (Mullers)	883
Fabrics and Yarns, Dyeing certain Colours on. (P. Hay and Park)	391
Fabrics, Printing on. (P. Jantsch)	513
Fibre, The Tendering of, by Tartaric Acid. (Scheurer)	148
Formation of R. sorcinol-green on. (Pokorny)	727
Goods, Paste or Size for. (P. Brown)	725
Goods, The Tendering of, by Iron Mordants used in Dyeing. (Scheurer)	148
Oil Industry in South Carolina. (T.R.)	992
Producing Fast Colours on. (P. Murray. From the Farb. vorm. Meister, Lucius, and Bruning)	883
Seed, Machinery for Cleaning. (P. Bibby)	1070
Seed Oil, Analysis of Lubricating Oils containing Blown. (Stillman)	286
Seed, Removing Fibre from. (P. Silcock)	945
Seed, The Proteids of. (Osborne and Voorhees)	828
Seed, Treatment of, for Removal of Fibres. (P. Thompson. From Stead)	820
Seeds, Apparatus for Cleaning. (P. Tattersall and Pearson)	803
Spontaneous Combustion of Oils Spread on. (Mackey)	1164
Stearin and Maize Oil. (Hart)	257
The Position of Lardwood on. (Bungert)	389
The Position of Colloid. (T.R.)	674
Council, Annual Report of	691
Coupling for Vessels containing Gases under High Pressure. (P. The Manchester Oxygen Co. and Jackson (illus.))	22
Crape, Artificial Production of Woollen. (Binder)	1192
Crapes, the Glossing of Woollen. (Kopp)	1193
Cream and Butter, Centrifugal Separators for. (P. Wahlin)	56
And Milk, Preserving, for Transit. (P. Casse)	537
Preparation and Employment of. (P. Monfort and Prior)	412
Production of. (P. Julien and Brin)	55
Cresosote, Apparatus for Burning. (P. Allen (illus.))	1050
Producing Esters from. (P. Abel. From von Heyden Nachfolger)	275
Cresosotes from Oak and Beech Wood, Composition of. (Béhal and Coisy)	1187
Qualitative Composition of Official Beech and Oakwood. (Béhal and Coisy)	1087
Cresol as an Anti-septic. (Lacroix-Hunkinbyendian)	273
Producing Esters from. (P. Abel. From von Heyden Nachfolger)	275
Cresols, Volumetric Estimation of the Three Isomeric. (Keppler)	1099
Crimbles, Manufacture of. (P. Digby)	158
Crushing Apparatus for Dry or Wet Materials. (P. Morel and Heimpel)	623
Cupene. Ethyl.	1086
Cupwine. Propyl.	1085

Damp-resisting Materials, (P) Goddard	1063
Darrieus' Theory of the Lead Secondary Battery, and Life of Plates, (Schoop)	1203
Deacon Process, Utilising the Broken Bricks of the, (P) Wyde and Williams	1059
Deaths, Lists of	1, 95, 197, 308, 447, 691, 927
Deductions from Analysis of India-rubber Articles, (Henriques)	70
Defecation Experiments with Beetroot Juice, (Herzfeld)	823
Densities of Solutions of Soda and Potash, (Pickering)	511
Derivatives of the Oxazine and Eurholine Series, (Lauth)	628
Dervaux Feed-Water Purifier, The, (Simon Thomas)	376
Dessicators, Stop-cock for Vacuum, (Erast) (illus.)	62
Designs on Waterproof Fabrics, Producing, (P) Frankenbure and Weber	725
Desulphurisation: The Action of Iron Sulphide on Various Metals	1063
Detergent Compound for Seaming Textiles, (P) Brothers	260
For Washing Linen, (P) Gross	261
Detonators. <i>See also</i> Fuses and Explosives.	
Developers, Manufacture of Photographic, (P) Abel, From The Actien Gesellschaft für Anilin Fab.	659
Dextrin, German Trade in (T.R.)	1112
Dextrins, Production of, (P) Abel, From Pieper	824
Dextrose, Cause of Biotation of, (Tollens)	105
Fermentation of, by Lavalactic Ferment, (Tate)	268
Diamido base and Tetrazo Colouring Matters therefrom, Manufacture of a, (P) Thompson and Moore	384
Base, Manufacture of a New, (P) Inray, From The Farb, vorm. Meister, Lucius and Bruning	384
Bases, Manufacture of New Unsymmetric, (P) Durand Huguenin and d'Andiran	143
Bases, Manufacture of Unsymmetric and Colouring Matters therefrom, (P) Durand Huguenin and d'Andiran	32
-Dibenzimidazols, Manufacture of, (P) Inray, From The Farb, vorm. Meister, Lucius and Bruning	941
-Naphthalene-Sulpho Acid, Production of, (P) Pitt, From Cassella and Co.	244
Diaphragm for Electrolytic Processes, Materials for, (P) Parker	257
Diaphthol or Quinaseptol, (Guinard)	903
Diastase, Degradation of Starch by the Action of, (Lintner and Düll)	53
Of Cereals, The, (Egaroff)	1080
Reichler's Artificial, (Egaroff)	1080
Utilisation of Flours Rich in, (P) Briant and Walker	55
Diaz Compounds and Nitrosamines, (Schraube and Schmidt)	508
Dibromogallianilide, Some Blue Lakes derived from, (Cazeneuve)	1095
Diffusibility of Certain Gases through Caoutchouc Membrane, (Reychler)	151

## PAGE

Diffusion Battery, Combustible Gases, arising from, (Dewald)	107
In Vacuo by Heckmann's Process, (Manger)	106
Uses, Advantages of Heating, with the Steam from the Diffusion, (Mehcher)	6
Juice, Filtration of, after Heating	107
Juice, Purification of, (Ludke)	107
Report of Polish Commission on, (Muller)	719
Use of Sulphurous Acid in, (Muller)	719
Digester, Ac., for Bones, Fat, Meat, Glue, &c., (P) Warner	94
Digoxine, Preparation of Pure, (Kahn)	84
Dihydroxy-Naphthalene-Sulpho Acids, Manufacture of, (P) Johnson, From The Badische Anilin- und Soda Fab.	512
Dimethylamine, The Carboxyl Derivatives of, (Lauth)	14
The Carboxylic Acids of, (Lauth)	19
Dinner, The Animal	5
Dioxydiphenylmethane, Manufacture of Colouring Matter from, (P) Durand, Huguenin and d'Andiran	143
Dioxy-naphthalene-Mono-Sulpho Acid, Manufacture of a New, (P) Inray, From The Badische Chemical Works	512
Dioxy-naphthalene-Mono-Sulpho Acid, Manufacture of a New, (P) Inray, From The Badische Chemical Works	512
Discharge and Resist Styles with Aniline Black, On, (Peyth)	183
Discharges and Resist on Silk, (Kochlin)	727
On Aniline Black, (Kochlin)	127
On Aniline Black Grounds, Coloured, (Kay)	107
Discolouration of Papers made from Sulphite Cellulose, (Muth)	18
Discussion on Comparative Analysis of Land (Paper by Schweizer and Langwitz)	118
On Comparative Results of Modern Systems of Sewage Treatment	108
Disenses of Wines, (Kays)	70
Disinfectant, A Liquid for Use on, (P) Elliot	152
For Railway Sanitation, Tests of a, (Sodgwick)	7
Disinfectants, (Class XI. H.) 57, 170, 271, 313, 518, 659, 751, 831, 909, 1081, 1116	
Improvements in, (P) McDougall	657
Manufacture of, (P) Alder Wright	171
Manufacture of, (P) Molyneux and Potts	415
Manufacture of Compounds for Preparation of, (Klever)	74
<i>See also under</i> Antiseptics.	
Disinfecting, and Apparatus therefor, (P) Hermite, Cooper, and Paterson	171
And Apparatus therefor, (P) Pitt, From La Société Pictet	900
Apparatus, (P) Andersson and Suström	190
Improvements in, (P) Hermite, Paterson and Cooper	170
Distillation (Destructive), Tar Products, Ac., (Class H.) 27, 219, 350, 507, 627, 719, 791, 871, 938, 1053, 1182	
Apparatus for Fractional, (Volney) (illus.)	102
Apparatus for Fractional, (Otto) (illus.)	837
Method of Fractional, Illustrated by the Investigation of Kerosene, (Wauklyn and Cooper)	627
New Apparatus for Fractional, (Varenne) (illus.)	601
Of Substances having a High Boiling Point, (P) Jaffé and Darmstadter	230
Of Vegetable Substances, Obtaining Products of, (P) Grumbacher	628
Retorts for Obtaining Products of, (P) Bowing	573
Distillers' Washes, Process and Apparatus for Drying, (P) Action Maschinenbauanstalt, vorm. Venneth and Eilenberger	827
Distilling Apparatus, (P) Lavy	751
Pure Cultivation Yeast, and Use of Antiseptics in, (Class)	345
Refrigerator for Use in, (P) Worsam	190
<i>See also under</i> Apparatus.	
"Doctor" for Printing Machines, An Aluminium Bronze	28
Dough, Manufacture of, from Cereals, (P) Gelinek	16
Drainage, Hermet's Process for Purifying, by Electricity	98
Dressing for Boots and Shoes, (P) James	747
Drier for Paints, Manufacture of, (P) Bedford	803
Drug Trade, Canada and the American, (T.R.)	95
Trade of Japan and the New Treaty, (T.R.)	990
Trade of New York and the Tariff, (T.R.)	101
Drying Apparatus. <i>See under</i> Apparatus.	
Dubbing or Dressing for Leather, (P) Emden	117
Dulcin, Obtaining of, (P) Wetter, From Riedel	42
Duties, The New Spirit, (T.R.)	140
Duty on Sulphate of Potash and Soda in Finland, (T.R.)	290
Dyeing, Calico Printing, Paper Staining, and Bleaching, (Class VI.) 34, 118, 218, 350, 513, 633, 729, 893, 880, 1045, 1057	
Apparatus, (P) Gessler	100
Apparatus, (P) Obermayer	128
Improvements in Turkey-red, (Eben and Specht)	110
Improvements in Turkey-red, (Muller)	63
Indigo Blues, Vats for, (P) Grune	143
Machines, (P) Weldon	243
Machines, Rotary, (P) Crabtree	284
Note on the Different Theories relating to, (Vignon)	220
On Substantive, (Weber) theories relating to, (Vignon)	120
Process, A New, (Bannett)	729

Polish for Furniture. (P) Horn .....	896
Polishing Medium. (P) Theil and Schmitz .....	497
Polypheols, some Blue Reactions of the. (Cazeneuve) .....	1098
Pomegranate Root, Alkaloids of the Bark of. (Ciancian and Silber) .....	416, 1217
Ponceau-Red Dye, a Japanese. (Scheurer) .....	598
Populus Tremula, The Tar of the Bark of. (Pharmakofsky) .....	794
Porcelain Industry at Limoges. (T.R.) .....	558
Process for Etching on. (P) Retzlaff .....	151
Producing Enamelled Letters and Designs on. (P) Hodan .....	884
Transparent Cement for. (Deutsch) .....	888
Portugal, the Preserved Fruit Industry of. (T.R.) .....	895
Potash and Soda, Densities of Solutions of. (Pickering) .....	514
Apparatus for Making Caustic. (P) Petrie .....	38
Deposits of Germany, Proposed Nationalisation of. (T.R.) .....	558
German Trade in Chromate of. (T.R.) .....	1110
German Trade in Prussiate of. (T.R.) .....	1111
Influence of Substances on Estimation of. (Dods) .....	1095
Manufacture of Caustic. (P) Garway .....	735
Manufacture of Peroanganate of. (P) Brock and Hunter .....	394
Potash—cont.	
Separation of Salts of, from Solutions of Magnesium Chloride. (P) Bell .....	9
Yellow Prussiate of, and Detection of Hydrocyanic Acid (Autenrieth) .....	814
Potashes, On the Valuation of. (Bendheim) .....	705
Potassium and Lead, Electrolytic Production of an Alloy of. (P) Vautin .....	714
And Sodium, Utilisation of Chlorides of. (P) Parker and Robinson .....	250
Arsenic, Reactions of Acid, with Metallic Salts. (Rochard) .....	732
Bisulphite, Action of, on Alcoholic Fermentation. (Bazzani) .....	266
Borohydroxide, Volumetric Determination of. (Schlotheim) .....	280
Carbide, Production of. (Mullhauser) .....	73
Chloride, Apparatus for Manufacture of, by Electrolysis. (P) Harter .....	810
Chlorate, Electrolytic production of. (Haussmann and Naschold) .....	885
Chloride, Apparatus for Electrolysis of. (P) Drake .....	887
Chloride, German Trade in. (T.R.) .....	1111
Cyanide, Exempt from Duty in China. (T.R.) .....	74
Cyanide, Tests on Extraction of Gold by Infuse. (Gwyder) .....	523
Determination of Reducing Action of Organic Substances in Water upon Permanganate of. (Zegen) .....	427
Iodate, Preparation of Pure. (Grosjean) .....	419
Nitrate, Occurrence of Perchlorate in. (Haussmann) .....	917
Nitrate, The Analysis of. (Hedrich) .....	979
Phosphate as Manure. (Meyer) .....	401
Salts, Influence of, on Nitrication. (Dumont and Chetelle) .....	672
Sulphate, German Trade in. (T.R.) .....	1111
Tanks for Electrical Decomposition of Chloride of, in Solution. (P) Richardson .....	616
Potato Pulp, Drying of, for Cattle Food, in Germany. (Delbrück) .....	965
Starch, Manufacture of, by Continual Flow System. (Bosdonnan) .....	759
Pottery. (Class XIII.) 39, 153, 251, 395, 518, 637, 735, 811, 888, 918, 1069, 1197	
Apparatus for Manufacture of. (P) Slack .....	1062
Decorating. (P) Shelley .....	949
Industries of the United States, Chemical Considerations on the. (Langenbeck) .....	153
Manufacture of. (P) Moran .....	1197
Manufacture of. (P) Worcester Royal Porcelain Co. and others .....	1197
Ovens for. (P) Hanquinn .....	1018
Ware, Means for Ornamenting. (P) Daulton and Rix .....	395
Powder, Improved Baking. (P) Brothers .....	752
Smokeless. (P) Brothers .....	1088
The Manufacture of Smokeless. (Guttmann (illus.) .....	575

Manufacture of. (P) Thompson, From Bismarck	4
Thick. (P) Thompson	516
Manufacture of. (P) Thwaite	528
Manufacture of, in the Open-Hearth. (Benjamin)	731
Manufacture of Manganese. (P) Hatfield	731
Manufacture of Open-Hearth, in Sweden. (Odelstrom)	1067
Method and Apparatus for Hardening and Tempering. (P) Fairfax and Bendin	1067
Plates, Pickling. (P) Kirkman	645
Plates, Preparation of, for Plating. (P) Chapman	644
Process for Surfaceing. (P) Thompson, From Kone-man	32
Production of. (P) Cochran and Fawcett	711
Results of High Treatment on Manganese and Iron. (P) Raze	641
Surfaces, Effecting the Protection of. (P) Bart and Bower	11
The Structure of. (Osmond)	1065
Sterilisation, Apparatus for. (P) Hussener	1215
Of Alimentary Liquids. (Kuhm)	1133
Still or Retort for use in Kjeldahl's Process. (P) Edwards	760
Stills, The Locality of Laboratory. (T.R.)	78
Stone and Marble, Manufacture of Artificial. (P) Baumeit and Pock	630
Bricks, Tiles, &c, Artificial. (P) Gaskell and Robinson	154
Manufacture of Artificial. (P) Grate	255
Manufacture of Artificial. (P) McLean and Wilson	888
Stoneware, Composition of. (P) Sellers and Rogers	888
Producing Enamelled Letters and Designs on. (P) Hodan	811
Stop-Clack for Vacuum Desiccators. (Ernst) (illus.)	62
Storage Batteries. See under Batteries	
Straw Cellulose, Manufacture of. (Heveridge)	101, 213
Stress, Effect of Mechanical, on Electrical Properties of Metals. (Gray and Henderson)	957
Effect of, on Corrosion of Metals. (Andrews)	1269
Strontium and Calcium, Separation of. (Browning)	282
Strumite. (Niederlander)	292
Styrene, Behaviour of, towards Vital's Atropine Reaction. (Menyaz)	981
Styandra glauca	897
Sublimite, Influence of Alcohol, &c, on Bacterioid Action of Corrosive. (Lense)	963
Succinic Acids formed in Fermentations, Estimation of. (Bau)	287
Succinimides, Production of Iodo-derivatives of, and of Substituted. (P) Murray, From The Farb. vorm. Meister, Lucius and Brunn	800
Production of Para-methoxy- and Para-methoxy-phenyl. (P) Murray, From The Farb. vorm. Meister, Lucius and Brunn	800
Sugar, Starch, Gum, &c. (Class XVI.)	52, 165, 263, 410, 533, 652, 718, 822, 965, 1076, 1210
Amounts of Coal and Steam required in Manufacture of. (Clasen)	824
Assay, Muffle for. (Schweitzer and Lenzwitz) (illus.)	858
Beet Returns of Germany. (T.R.)	202
Beetroot Growing Experiments in 1893. (Schack Sommer)	213
Camphor as a Reagent for. (Seitz)	843
Contained in Massicot, Quantity of Crystalline. (Nylen)	1210
Content of Tanning Materials, &c. (Von Schroeder and others)	1101, 1227
Continuous Refining or Bleaching of, and Apparatus therefor. (P) Prancey	265
Decomposition of, during Evaporation. (Lexal)	965
Decomposition of, during Evaporation. (Strohmer)	1210
Decomposition of Invert, by Alkalis. (Prinsen-Georgius)	410
Estimation of. (Von Schroeder, Bartel, and Schmitz-Dumont)	1101
Factories, Recovery of Nitrates in	729
Factories, Seum Fermentation in Javmose. (Gurlings)	823
Factory, Loss of Heat in the Steam Engines of a. (Clasen)	718
Formation of Cane, during Germination of Barley and Ripening of the Apple. (Lindet)	750
Formation of, in the Liver. (Cavazzani)	845
Gravimetric Estimation of Cupric Reducing Power of Invert. (Bortrager)	1236
In Beetroots, Determination of Crystallisable. (Pellet)	669
In Beetroots, Estimation of. (Kroeker)	823
Industry, Improvements in the Beetroot. (Jarkovsky)	965
Industry of South Africa, The. (T.R.)	675
Industry of Sweden, Beet-. (T.R.)	556
Influence of Calcium Salts on Yield of, from Massicot. (Szyfer)	965
Influence of Cane, on Valuation of Malts and Worts. (Prior)	1080
Influence of Lead Acetate on Cupric Reducing Power of Invert. (Bortrager)	1230
Influence of Percentage of Fat in Beet Seed on Richness of Beets in. (Doerflinger)	410
Influence of Volume of Lead Acetate Precipitate on Titration of. (Bortrager)	1230
Inversion of, by Glycerol. (Bord)	1211
Juice, Continuous "First Saturation" of. (Francis) (illus.)	166
Juice, Continuous Saturation of. (Rebock)	749
Juice, Defecation of Diffusion, with Pulverised Slaked Lime (Mittelmann)	166
Juice, Defecation and Filtration of. (Mittelmann)	965
Juice, Filter for Diffusion. (Bouvier)	167
Juice, Filtration of Diffusion, after Heating	749
Juice, Precipitates obtained in Evaporating. (Shorey)	750

	PAGE		PAGE
Tanning— <i>cont.</i>		Theory of Mordant Dyeing	
Materials and Extracts, Sugar Content of, Von Schroeder and others	1101, 1227	Thermometer for High Temperatures, a New	1227
Materials, Water-Content of Common, (Von Schroeder)	1072	For High Temperatures, Mercury, (Mahlke)	62
Materials, Analysis of, (Felsing)	426	For High Temperatures, Mercury, (Recklinghausen)	71
Materials, Extraction of, (Schroeder and Bartel)	649	Thermostatic Instruments, (P) Beckes, From Gregory	71
Materials Qualitative Determination of, (Procter)	187	The Thermostat, Improvements in, (P) Shells	167
Matter, On the Estimation of, (Procter) (illus.)	494	"Thomas' Metallurgical Process, Improvements in the, (P) Wild	161
Sprays, (Reimsch)	651	Thymol Acetate, Constitution of the Methyl, (C) and (J)	84
With Extracts, (Vilhou)	746	Tiles, Manufacture of, (P) Gaskell and R. (illus.)	151
Tannins, Preparation of Oak, (Trimble and Peaseck)	59	Manufacture of Glazed, (P) Martin	46
Tapestry, Obtaining a Substitute for, (P) Lake, From The Fratelli Mora	34	Timber, Preservation of, from the Attacks of Insects, (De Garmun)	43
Tar Products (Class III.)	27, 213, 350, 507, 627, 719, 791, 871, 938, 1053, 1182	Tin and Cadmium, Electrolytic Separation of, (Schmuck)	283
Distillation of Birch, from Pines, (Hirschmann)	423	And Copper, Electrolytic Separation of, (Schmuck)	280
From Fuel, Apparatus for Obtaining, (P) Mond (illus.)	938	Consumption of, in India, (T.R.)	1116
German Trade in, (T.R.)	1113	Plate, Utilization of Old Articles of, (P) Gentsch	40
Of Pinus Maritima, (Reinard)	1188	Recovery of, from Plates and Waste, (P) Krebs and Harper	641
Of the Bark of Populus Tremula, (Pharmakofsky)	794	Recovery of, from Scrap and Metal, (P) Hurd	122
Pines, (Reinard)	1188	Resist for Silk, (Koechlin)	727
Valves for, (P) Cripps	508	Separation and Estimation of, in Alloys, (Menein)	1224
Washers for Separating, from Coal-Gas, (P) Cripps (illus.)	379	Separation of Lead from, (Jannasch and Reimann)	56
Tars, Mixing for Use for Heating or Lighting Purposes, (P) Sahlstrom and Farr	130	Solutions or Platines, Volumetric Estimation of Lead in, (Bayr)	420
Tariff Changes and Customs Regulations	74, 182, 280, 430, 550, 672, 703, 816, 903, 989, 1232	Sulphide, White Form of, Soluble in Ammonium Carbonate, (Schmidt)	1261
Changes in Canada, (T.R.)	846	Temperature of Fusion of, (Bogdanoff)	1053
Changes in Guatemala, (T.R.)	989	Tinctures and Essences, Revenue Concessions on Export of, (T.R.)	772
Changes in Jamaica, (T.R.)	1232	General Order as to Export of, (T.R.)	183
Changes in Norway, (T.R.)	290	Recovery of Residual, from Mares, (Parker) (illus.)	973
Changes in Victoria, (T.R.)	430	Table of Results of Estimating, Gravimetrically and Volumetrically	984
Law, Proposed New, (T.R.)	78	Titre of Tallow, Estimation of the, (Wolffbauer)	908
Of the United States, (T.R.)	847, 901	Tobacco-Juice, Extraction of Nicotine from, (T.R.)	850
Tarragon, Essence of, and its Transference into Anethol, (Grimaux)	658	Pipes, Porous Material suitable for, (P) Smith	395
Tartar Emetic Resist for Silk, (Koechlin)	727	Treatment of, to Prevent the Injurious Action of Nicotine, (P) Lake, From Gerold and Wendl	275
Tartaric Acid, Decomposition of, by Sunlight, (Seckamp)	810	Tolyl-Antipyrine, Derivatives of, (Ebert)	79
Acid, German Trade in, (T.R.)	1111	Tomatoes, Detection of Eosin in Coloured, (McElroy and Bicklow)	284
Acid in Wines, Methods of Estimating Free, (Carpene)	908	Tortimolite Process, The	89
Acid, Manufacture of, in Sicily, (T.R.)	676	Toxers and Ducts, Motion of Gases in, (Jurisch)	513
Acid, Spontaneous Formation of Pyruvic Acid from, (Otto)	733, 733	Trachymene Australis	897
Acid, Supposed occurrence of Free, in Wine, (Carpene)	1080	Tracing Cloth, Production of Material for Use as, (P) Goodwin	803
Acid, The Tendering of Cotton Fibre by, (Scheurer)	118	Trade of Germany in 1891, The Foreign, (T.R.)	290
Materials, Italian Trade in, (T.R.)	677	Trade Report, 71, 182, 280, 430, 550, 672, 703, 846, 903, 989, 1108, 1232	
Materials, Production of, in Italy, (T.R.)	1234	Train Oil, Detection of Paraffin and "Lubricating Oil" in Distillate from, (P) Engler and Sauer	45
Tatlock's Process for Estimation of Potash, (Bodsi)	1005	Transvaal Mines, The Cyanide Process in the, (Feldmann)	951
Tea and Coffee, Preparing Extracts of, and Utilising By-Product, (P) Sonstadt	270	Treaty between Russia and Germany, Proposed New Commercial, (T.R.)	289
Tea-Seed Oil, (T.R.)	79	Trigonellin, Occurrence of, in Seeds of Pisum Sativum and Cannabis Sativa, (Schulze and Frankfurt)	737
Telluric Acid, Physiological Action of, (Bokorny)	289	Trihydroxy-naphthalene Monosulpho Acid, Production of a, (P) Newton, From The Farb, vorm. Bayer and Co.	1054
Temperature, Determination of High, by Fusion Tests, (Schneider)	702	Trinitroresorcinol Smokeless Drying Powder, Employment of, (P) Hauff	975
Influence of, on the Tensile Strength of Metals, (Rudeloff)	520	Triphenylmethane Colouring Matters, Behaviour of, to Nascent Bromine, (Vaubel)	876
Of Bread as it Comes from the Oven, (Balland)	55	Tube for Polarimetric Observations, (Hamp)	278
Of Fermenting Liquids, Apparatus for Regulating, (P) Collins	890	Tubes for Heating, Cooling and Evaporating Apparatus, (P) Thompson, From Dumas	716
Of Fusion of Tin, (Bogdanoff)	1006	For Heating, &c., (P) Dumas	690
Temperatures, Mercury Thermometer for High, (Mahlke)	62	For Heating Liquids, Metallic, (P) Goldthorp	929
Mercury Thermometer for High, (Recklinghausen)	61	Of Covered Glass, Manufacture of, (P) Browne, From Kastner	199
Tephrosia Purpurea and Rosen	857	Tungsten, Electrometallurgy of, (T.R.)	14
Ternary Alloys, On certain, Part VIII, (Alder Wright)	521	Turkistan, Salt Discovery in, (T.R.)	869
Terpene Series of Hydrocarbons, Discussion on Production of Oil-Gas from	501	Turkey, Importation of Patent Medicines into, (T.R.)	508
Series, Production of Gas from Pure Members of the, (Tocher) (illus.)	231	Red Dyeing, Improvements in, (Erhan and Specht)	159
Terpenes in Petroleum, (Zaloziecki)	1187	Red Dyeing, Improvements in, (Muller)	159
The Aerial Oxidation of, (Kinzett)	275	Red Oils, Constitution of, (Julliard)	823
Terra-Cotta Blocks, Moulds for, (P) Doulton and Carr	948	"Turkish Honey," The So-called, (Ejano)	672
Cottas, Manufacture of, (P) Schliekeyson	154	Turpentine, Buying, by Weight, (T.R.)	1115
"Tesu," The Colouring Matter of the Indian Dyestuff, (Hummel and Cavallo)	144	Determination of Oil of, in Alcohol, (Pohl)	427
Testers, Improvements in Milk, (P) Pedersen	56	Oil, German Trade in, (T.R.)	1112
Textile Fibres, Influence of Structure of, upon Absorption of Colouring Matters, (Georgievics)	807		
Fibres, Process for Retting, Cleansing, and Treating, (P) Grischwitz	1053		
Textiles, (Class V.)	32, 148, 248, 384, 312, 632, 725, 802, 880, 944, 1056, 1192		
Apparatus for Drying and Carbonizing, (P) Dasse and Fettweis	1192		
Apparatus for Dyeing and Washing, (P) Labhardt	391		
Apparatus for Soaping and otherwise Treating, (P) Jackson and Hunt	248		
Detergent Compound for Securing, (P) Brothers	260		
Dyeing, (P) Lake, From Michaelis and Co.	634		
Dyeing, in Cops or Spools, (P) Erhan and Specht	1194		
Dyeing, Sizing, Bleaching, &c., (P) Smith	513		
Method and Apparatus for Dyeing, (P) Lake, From Mattei	728		
Rendering, Waterproof and Flame-proof, (P) Rous and West	725		
Research on the Hygroscopic Properties of, (Schloessing, jun.) (illus.)	146

Plates, Treatment of Lithographic. (P) Forrest and Bucholz .....	527
Preparing Solutions carrying Salts of. (P) Choate .....	335
Process and Apparatus for Extraction of. (P) Lynen .....	402
Produced by Electrolysis, Treatment of. (P) Wright and Ramond .....	1067
Producing Metallic. (P) Choate .....	741
Production of, in Germany. (T.R.) .....	74
Recovery of, from Waste Galvanised Metal. (P) Hayward .....	401
Resist for Silk. (Koschlin) .....	727
Smelting at the Bertha Works, Virginia. (Moxham) .....	41
Smelting in the Blast Furnace, Hempel's Experiments on. White, German Trade in. (T.R.) .....	814
	1115

## INDEX OF NEW BOOKS.

	PAGE		PAGE
Analyses of Twelve Thousand Prescriptions. W. Martindale . . . . .	768	Laboratory Guide, The. A. H. Church . . . . .	769
Alchemical Essence and the Chemical Element, The. M. M. Pattison Muir . . . . .	289	Law and Theory in Chemistry. D. Carnegie . . . . .	549
Chemiker-Kalendar, 1895. Dr. R. Biedermann . . . . .	1107	Micro-Organisms in Water. Percy Frankland and Mrs. Percy Frankland . . . . .	671
Chemisch-Technisches Repertorium. Dr. E. Jacobsen 182, 845, 1232		Mineral Resources of the United States, Calendar Year 1893. D. T. Day . . . . .	846
Descriptive Catalogue of Essential Oils and Organic Chemical Preparations. F. B. Power . . . . .	989	Nature's Hygiene. C. T. Kingzett . . . . .	768
Dictionary of the Active Principles of Plants: Alkaloids; Bitter Principles; Glucosides: Their Sources, Nature, and Chemical Characteristics. C. E. Sohn . . . . .	72	Odorographia: A Natural History of the Raw Materials and Drugs used in the Perfume Industry. J. Ch. Sawyer . . . . .	429
Die Chemische Industrie auf der Columbianischen Weltausstellung zu Chicago und in den Vereinigten Staaten von Nord America im Jahre 1893. Dr. Bosse, erstattet von Dr. O. N. Witt . . . . .	768	Practical Paper-Making. G. Clapperton . . . . .	549
Die Fabrikation von Schwefelsaurer Thonerde. Dr. K. W. Jurisch . . . . .	1108	Principles and Practice of Agricultural Analysis. Harvey W. Wiley . . . . .	289
Die Maschinellen Hilfsmittel der Chemischen Technik. A. Parnicke . . . . .	1108	Rasa-Ranga-Rahasya. M. G. Deshmukh and T. K. Gajjar . . . . .	988
Die Selbstentzündung von Schiffsladungen, Baumwolle, und anderen Faserstoffen, Steinkohlen, Heuhaufen, Tabak, &c. Dr. L. Hapke . . . . .	289	Rise and Development of Organic Chemistry, The. C. Scharlemmer. Edited by A. Smithells . . . . .	1106
Einführung in das Studium der Qualitativen Chemischen Analyse. C. Friedheim . . . . .	1107	Select Methods in Chemical Analysis (Chiefly Inorganic). W. Crookes . . . . .	845
Engineering Chemistry. H. J. Phillips . . . . .	549	Systematic Survey of the Organic Colouring Matters. G. Schultz and P. Julius . . . . .	671
Gas Engineer's Laboratory Handbook, The. J. Hornby . . . . .	429	Tabellarische Uebersicht über die Künstlichen Organischen Farbstoffe, &c. Dr. Adolf Lehner . . . . .	73, 429, 768, 1231
Grundriss der Pharmakognosie. F. A. Flückiger . . . . .	429	Tannins, The. H. Trimble . . . . .	559
Handbook of Gold Milling. A. H. Louis . . . . .	429	Technisch-Chemisches Jahrbuch, 1892-1893. Dr. R. Biedermann . . . . .	845
Handbuch der Anorganischen Chemie. Dr. O. Dammer . . . . .	1231	Teinture et Impression. M. Prud'homme . . . . .	429
Handwörterbuch der Pharmacie. A. Brestowski . . . . . 182, 768, 989		Treatise on Chemistry. A. Sir H. E. Rose and C. Scharlemmer. Vol. I. The Non-Metallic Elements. New Edition. Revised by Sir H. E. Rose, H. G. Colman, and A. Harden . . . . .	1107
Jahrbuch der Chemie. R. Meyer . . . . .	846	Universal Exposition at Paris, 1889. Report on Chemical and Pharmaceutical Products. S. B. Newbury . . . . .	289
Jahresbericht über die Leistungen der Chemischen Technologie, mit besonderer Berücksichtigung der Gewerbestatistik für das Jahr 1893. Dr. F. Fischer . . . . .	671	Water Analysis. J. A. Wanklyn and E. T. Chapman. Ninth Edition. J. A. Wanklyn . . . . .	768
Jahres-Rundschau über die Chemische Industrie und deren wirtschaftliche Verhältnisse für das Jahr 1893. Ein übersichtlich geordneter Bericht über die Fortschritte der Chemischen Gross- und Klein-Industrie, &c. Dr. A. Bender . . . . .	671	Watts' Dictionary of Chemistry. Revised and Re-written by M. M. Pattison Muir and H. Forster Morley . . . . .	989

# LIST OF ERRATA FOR 1894.

Page.	Column.	Line.	Description.
52	2	41	For "Tannet" read "Tannet."
62	1	28	From top: for "phosphorous" read "phosphorus."
165	2	16	From bottom: for "Edemann" read "Telemann."
166	1	27	From top: for "Mittelmann" read "Mittelmann."
171	1	37	From top: for "pyrozollol" read "pyrozollol."
255	1	24	From top: for "slaxwood" read "slagwood."
428	1	53	From top: for "techn" read "techn."
428	1	22	From bottom: for "chromoscope" read "chronoscope."
428	1	26	From bottom: for "chromoscope" read "chronoscope."
652	1	2	From top: insert "Gis."
760	..	..	The third Abstract from top should be under "XXIII., Apparatus, &c."
780	2	31	From bottom: for "connection" read "convection."
780	2	13	From bottom: for "when" read "where."
818	2	17	From bottom: for "Bewitt" read "Hewett."
820	2	17	From bottom: for "Gentzsch" read "Gentzsch."
823	1	9	From top: for "60" read "69° R."
824	1	20	From top: for "degration" read "degradation."
824	1	24	From top: for "Prinsen Gurlugs" read "Prinsen Geerlugs."
842	2	10	From top: for "Trommedorffs" read "Trommsdorffs."
846	1	23	From top: for "1894" read "1895."
891	2	24	From bottom: for "as" read "whilst."
945	2	9	From top: for "Georgievics" read "Georgievics."
965	2	17	From top: for "Mittelman" read "Mittelmann."
1026	..	..	Morzan's Tabular Scheme for Iron Ore Analysis, col. 1, under sub-heading <i>Reagents</i> : for "HCl" read "HF."

# LIST OF COUNCIL AND OFFICERS.

---

## *President.*

E. C. C. Stanford, Glenwood, Dalmeir, N.B.

## *Vice-Presidents.*

Sir F. A. Abel, Bart., F.R.S., 40, Cadogan Place, S.W.

Horace T. Brown, F.R.S., 74, Addison Road, Kensington, W.

H. Brunner, Holly Mount, Huyton, Liverpool.

Wm. Crowder, 271, Evering Road, Upper Clapton, E.

Sir John Evans, K.C.B., F.R.S., Nash Mills, Hemel Hempstead, Herts.

Dr. F. Hurter, Holly Lodge, Cressington Park, Liverpool.

E. K. Muspratt, Seaforth Hall, near Liverpool.

Dr. W. H. Perkin, F.R.S., The Chestnuts, Sudbury, Harrow.

Prof. J. Emerson Reynolds, M.D., F.R.S., 70, Morehampton Road, Dublin.

Jno. Spiller, 2, St. Mary's Road, Canonbury, N.

Prof. T. E. Thorpe, F.R.S., Royal College of Science, South Kensington, S.W.

Sir John Turney, Springfield, Alexandra Park, Nottingham.

## *Ordinary Members of Council.*

R. Forbes Carpenter, Bent Terrace, Prestwich, near Manchester.

Prof. Frank Clowes, D.Sc., University College, Nottingham.

Dr. Chas. Dreyfus, Clayton, Manchester.

Thos. Fairley, 16, East Parade, Leeds.

Prof. G. G. Henderson, D.Sc., 204, George Street, Glasgow.

C. C. Hutchinson, Engineering Works, Stratford, E.

Robt. Irvine, Royston, Granton, Edinburgh.

John Pattinson, 75, The Side, Newcastle-on-Tyne.

Manning Prentice, Stowmarket, Suffolk.

Boverton Redwood, 4, Bishopsgate Street Within, London, E.C.

A. Gordon Salamon, 1, Fenchurch Avenue, E.C.

Thos. Tyrer, Stirling Chemical Works, Stratford, E.

## *Ex-officio Members of Council.*

Alf. Allhusen, Gateshead-on-Tyne.

J. Carter Bell, Bank House, The Cliff, Higher Broughton, Manchester.

Eustace Carey, Browside, Gateacre, near Liverpool.

Dr. J. T. Dunn, The School, Gateshead-on-Tyne.

John Heron, 74, North Side, Clapham Common, S.W.

Dr. Chas. A. Kohn, University College, Liverpool.

Ivan Levinstein, 21, Minshull Street, Manchester.

J. Stanley Muir, Chemical Laboratory, The University, Glasgow.

J. M. C. Paton, Messrs. Manlove, Alliott, & Co., Nottingham.

H. R. Procter, Yorkshire College, Leeds.

Prof. A. Smithells, Yorkshire College, Leeds.

Wm. Thorp, B.Sc., 24, Crouch Hall Road, Crouch End, N.

R. Lloyd Whiteley, University College, Nottingham.

## *Honorary Treasurer.*

E. Rider Cook, East London Soap Works, Bow, E.

## *Honorary Foreign Secretary.*

Ludwig Mond, F.R.S., 20, Avenue Road, Regent's Park, N.W.

## *General Secretary.*

Chas. G. Cresswell, Palace Chambers, Westminster, S.W.

## *Editor.*

Watson Smith, University College, London, W.C.

# LIST OF MEMBERS.

## A

Abbott, John, Braemar House, Lancaster Gate, Hyde Park, W.  
 Abel, Sir F. A., Bart., F.R.S., 40, Cadogan Place, London, S.W.  
 Acland, Sir H. W., Bart., F.R.S., Radcliffe Library, Oxford.  
 Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick, near Birmingham.  
 Adams, M. A., Ashford Road, Maidstone, Kent.  
 Alcock, S. R., Minas de Rio Tinto, Provincia de Huelva, Spain.  
 Addie, J., Langloan Ironworks, Coathridge, N.B.  
 Adriance, John S., 231, Broadway, New York, U.S.A.  
 Affleck, Dr. J., Mill House, Woolton, near Liverpool.  
 Aikman, Charles M., 128, Wellington Street, Glasgow.  
 Aitken, Dr. A. P., 57, Great King Street, Edinburgh.  
 Aitken, J. B., Gerard's Fold Chemical Works, Widnes.  
 Albright, G. S., The Elms, Park Road, Edgbaston.  
 Albright, W. A., Mariemont, Edgbaston, Birmingham.  
 Alcock, Jno. W., Central Brewery, Mott Street, Birmingham.  
 Aldrick, Edwin John, 26, Alpha Road, West Ferry Road, Millwall, E.  
 Alexander, W. T., 29, Booth Street, Moseley Street, Manchester; and Crummock Bank, Victoria Crescent, Eccles.  
 Allan, F. H. Tielke, Portobello House, Wakefield.  
 Alldred, C. H., 6, Heavitree Road, Plumstead Common, Kent.  
 Allen, A. H., Sydenham Cottage, Park Lane, Sheffield.  
 Allen, Edw. W., Dover Mills, Glossop, Derbyshire.  
 Allen, G. J., Ivy House, Bolton Road, Pendleton, Manchester.  
 Allen, J., 164, Upper North Street, Poplar, London, E.  
 Allen, R. L., Roseleigh, Heaton Chapel, near Stockport.  
 Allen, Walter S., 24, West Street, Boston, Mass., U.S.A.  
 Allen, Walter W., c/o The Pueblo Smelting and Refining Co., Pueblo, Colorado, U.S.A.  
 Allen, Wm., Evenley Hall, Brackley, North Hants.  
 Allen, Wm. N., 2, Chesnut Street, Philadelphia, Pa., U.S.A.  
 Allhusen, A., Gateshead-on-Tyne.  
 Allibon, G. H., c/o Richardson Bros. & Co., 30, Donegall Place, Belfast.  
 Alliot, J. B. Messrs. Manlove, Alliot, and Co. Ltd., Nottingham.  
 Alpiar, Agop, Smyrna, Asia Minor.  
 Alsborg, M. (Sondheim, Alsborg, & Co.), P.O. Box 2437, New York, U.S.A.  
 Ambler, Chas. T., Monghyr, E. I. Railway, Bengal, India.  
 Anderson, Eugene E. J., 4, Muirpark Gardens, Partick, Glasgow.  
 Anderson, Geo. B., 630, Scotswood Road, Newcastle-on-Tyne.  
 Anderson, J. M. T., Explosives Co. Ltd., Stowmarket, Suffolk.  
 Anderson, Robt. T. R., 618, Gallowgate Street, Glasgow.  
 Anderson, W. Carrick, jun., Mavisbank, Partick Hill, Glasgow.  
 Anderson, Wm. Francis, 11, Montague Road, Dalston, N.E.  
 Anderton, G. H., Howendyke, Howden, Yorks.  
 Andrews, C. W., Mass. Inst. of Technology, Boston, Mass., U.S.A.

Angell, J., 6, Beaconsfield, Derby Road, Fallowfield, Manchester.  
 Annandale, C. J. R., 265, Queen's Road, Peckham, S.E.  
 Annandale, J. H., Polton, Midlothian, N.B.  
 Annison, R. H., 16, Water Lane, Tower Street, London, E.C.  
 Ansdell, G., 10, Gledhow Gardens, South Kensington, S.W.  
 Ansdell, T. C., Kearsley Cottage, Farnworth, Bolton.  
 Anselm, Dr. Fritz, c/o Clayton Aniline Co., Ltd., Clayton, Manchester.  
 Archbold, Dr. George, 121—123, Front Street, New York City, U.S.A.  
 Archbutt, L., 11, Charnwood Street, Derby.  
 Arding, Francis, 5, Jeffreys Square, St. Mary Axe, London, E.C.  
 Armstrong, Rt. Hon. Lord, F.R.S., Newcastle-upon-Tyne.  
 Arrol, Jas., jun., Joao Branco, Marahu, Bahia, Brazil; and (subs.) 8, Fir Park Terrace, Dennistoun, Glasgow.  
 Aron, S. B. Asher, Wemmer Gold Mining Co., Johannesburg, S.A.R.  
 Ashburn, Wm. B., Newton Bank Printworks, Hyde, Cheshire.  
 Ashplant, Wm. Gilbert, Palmer House, Torrington, North Devon.  
 Ashton-Bost, W.D., Cartvale Chemical Works, Paisley, N.B.  
 Ashwell, H., 91, Waterloo Crescent, Nottingham.  
 Ashwell, J. H., 91, Waterloo Crescent, Nottingham.  
 Ashworth L., Sunny Lea, St. Anne's-on-Sea, Lancashire.  
 Atkins, C. E., East Ham House, East Ham, Essex.  
 Atkinson, A. J., 44, Loudoun Square, Cardiff.  
 Atkinson, R. W., 44, Loudoun Square, Cardiff.  
 Attfield, Dr. J., F.R.S., Ashlands, Watford, Hertfordshire.  
 Auer, Dr. H., 71, Island Road, Garston, Liverpool.  
 Auerbach, Dr. C. G., 7, Breite Strasse, Ludwigshafen a/ Rhein, Germany.  
 Austen, Prof. Peter T., 876, President Street, Brooklyn, N.Y., U.S.A.  
 Aykroyd, H. E., Ashwell, Toller Lane, Bradford, Yorks.

## B

Babington, Percival, 6, Grange Terrace, Weymouth.  
 Bache, Arthur E., 7, Park Row, Greenwich, S.E.  
 Bachke, Anton S.O., Røros Vaerke, Røros, Norway.  
 Bailey, Edwin M., 6, Pumpherson, Mideclder, N.B.  
 Bailey, Dr. G. H., Owens College, Manchester.  
 Bailey, Richard D., City Brewery, Gloucester.  
 Bailey, Thos., 25, High Street, Hull.  
 Bailey, Dr. T. L., University College, Brownlow Street, Liverpool.  
 Bailey, W. H., Albion Works, Salford, Manchester.  
 Bailey, Walter P., 8, South Park, Ilford, Essex; and (Journals) c/o G. W. Welton, Seville, Spain.  
 Bainbridge, Herbert A., Union Club, Trafalgar Square, London, S.W.  
 Baird, H. Harper, 14, Cross Street, Hatton Garden, London, E.C.  
 Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E.  
 Bairstow, John, 32, Sealand Road, Chester.  
 Baker, Harry, Vicarage Road, Langley Green, near Birmingham.

- Baker, Julian L., Stamford, Hendham Road, Upper Tooting, S.W.
- Baker, Theodore, The Warner House, Emporium, Pa., U.S.A.
- Bald, J. H., Braddock, Pa., U.S.A.
- Bale, Fred., Coventry Hospital, Droitwich.
- Ball, Arthur, 137, Tufnell Park Road, London, N.
- Ballard, Ernest, Colwall, Great Malvern.
- Ballard, E. G., Newton Lane, Hoole, Chester.
- Ballauntine, H., 260, Renfrew Street, Glasgow.
- Ballingier, Jno., Free Library, Cardiff.
- Baly, E. C. C., Bank of England, London, E.C.
- Bamber, H. K., 9, Victoria Street, London, S.W.
- Banister, H. C., G. 14, Exchange Buildings, Liverpool.
- Banks, Arthur J., c/o F. W. Fellowes, 61, Chancery Lane, London, W.C.
- Banks, Jno. H., c/o Ricketts and Banks, 104, John Street, New York, U.S.A.
- Banner, Samuel, 4, Ivanhoe Road, Liverpool.
- Bannister, R., The Laboratory, Somerset House, London, W.C.
- Bannister, W., Victoria Lodge, Cork, Ireland.
- Barbour, T. F., 35, Robertson Street, Glasgow.
- Barelay, H., Calder Ironworks, Coatbridge, N.B.
- Barden, Alf., Far Bank, Shelley, near Huddersfield.
- Bardsley, Robt., c/o Jewsbury and Brown, 44, Downing Street, Manchester.
- Barford, E. A., New Bedford Road, Luton, Beds.
- Barnes, Edw. A., c/o The National Explosives Co., Lim., Hayle, Cornwall.
- Barnes, H. J., Phoenix Chemical Works, Hackney Wick, E.
- Barnes, J., Marl Terrace, Acreington, Lancashire.
- Barnes, Jonathan, 1, Trafalgar Street, Great Clowes Street, Manchester.
- Barr, J., Dinting Vale, Dinting, Derbyshire.
- Barnacelough, T. C., 20 Bucklersbury, London, E.C.
- Barnacelough, Wm. H., 47, Disraeli Road, Forest Gate, E.
- Barratt, Alex., Bronheulog, Glanydow, Mostyn, N. Wales.
- Barrett, Arthur A., Isola Perroni, Piazza del Collegio Militare, Messina, Sicily.
- Barrie, D. McLaurin, c/o Langlaange G.M. Co., P.O. Box 98, Johannesburg, S.A.R.
- Bartlett, Frank L., c/o American Zinc Lead Co., Cañon City, Colorado, U.S.A.
- Barton, G. E., Aetna Powder Works, Miller, Lake Co., Indiana, U.S.A.
- Bassett, H., 26, Belitha Villas, Barnsbury, N.
- Batchelor, Telford C., 8, Baron's Court Road, West Kensington, W.
- Bate, William, c/o National Explosives Co., Ltd., Hayle, Cornwall.
- Bateman, Jno., c/o J. C. and J. Field, Lim., Lambeth Marsh, S.E.
- Bateson, Percy, Emsworth, Wavertree, Liverpool.
- Batty, R. B., Wharnccliffe, Erdington, near Birmingham.
- Bavay, Aug. de, Victoria Brewery, Melbourne, Australia.
- Baxter, Henry, The Tower, Rainhill, Lancashire.
- Baxter, W. H., 11, High Road, Streatham, S.W.
- Bayne, Prof. Jas., Chemical Laboratory, Royal Veterinary College, Camden Town, N.B.
- Baynes, J., Royal Chambers, Seale Lane, Hull.
- Beach, E. J., 1183, Locust Street, Dubnque, Iowa, U.S.A.
- Beadle, Clayton, 4, New Court, Lincoln's Inn, W.C.; and Beadonwell, Belvedere, Kent (Journals).
- Bealey, Adam C., c/o R. Bealey & Co., Radcliffe, Lancashire.
- Beanes, E., Moatlands, Paddock Wood, Kent.
- Beaven, E. S., 5, Boreham Terrace, Warminster, Wilts.
- Beck, H., 22, Bush Lane, E.C.
- Beckett, G. H., c/o Alf. Nobel, San Remo, Italy.
- Beckett, J. H., Corbar Hill House, Buxton.
- Beclen, Lezin A., McCall Post Office, Parish of Ascension, Louisiana, U.S.A.
- Bedford, Chas. S., Broomleigh, Chapel Lane, Headingley, Leeds.
- Bedford, J., Woodhouse Cliff, Leeds.
- Bedford, Jas. E., Messrs. Wood and Bedford, Kirkstall Road, Leeds.
- Bedson, Prof. P. P., Durham College of Science, Newcastle-on-Tyne.
- Beilby, G., St. Kitts, Slateford, N.B.
- Bell, C. Lowthian, Linthorpe, Middlesbrough-on-Tees.
- Bell, G., 59, Sandown Lane, Wavertree Road, Liverpool.
- Bell, H. S., 2, St. Anne's Park Villas, Wandsworth, S.W.
- Bell, Sir Lowthian, Bart. F.R.S. (Journals), Rounton Grange, Northallerton; and (subs.) c/o Bell Bros., Middlesbrough.
- Bell, J. Carter, Bank House, The Cliff, Higher Broughton, Manchester.
- Bell, J. Ferguson, Stafford.
- Bell, Percy Carter, 13, Park Row, New York, U.S.A.
- Bell, T. Hugh, Middlesbrough-on-Tees.
- Bendix, D., The British Alizarin Co., Limited, Silvertown, Victoria Docks, London, E.; Journals to 371, Romford Road, Forest Gate, E.
- Benger, F. B., The Grange, Knutsford, Cheshire.
- Benjamin, Dr. M., c/o D. Appleton & Co., 1, Bond Street, New York, U.S.A.
- Bennett, Thos., Birch Vale, near Stockport.
- Bennie, J. W., 2, Limesford Road, Nunhead, S.E.
- Benson, Surgeon-Major P. H., Mysore City, South India.
- Bentley, J. W., Stakehill Works, Castleton, Manchester.
- Bentz, Ernest, 147, Bishop St., Alexandra Park, Manchester.
- Beringer, J. J., Basset Road, Camborne, Cornwall.
- Berk, Fred. W., 1 Fenchurch Avenue, London, E.C.
- Bernard, Jas., jun., Quinta do Valle Formoso, Braço de Prata, Lisbon.
- Bernays, J., 96, Newgate Street, London, E.C.
- Berry, E. E., Casa Balestra, Bordighera, Italy.
- Berry, G. F., Atlas Chemical Works, West Ferry Road, Millwall, E.
- Best, Dr. T. T., St. Helens, Lancashire.
- Bevan, E. J., 4, New Court, Lincoln's Inn, London, W.C.
- Bevan, J. Williams, Chemical Works, Temple Street, Dublin.
- Bevan, S. Howel, Goring Road, Llanelly, South Wales.
- Beveridge, J., Northfleet Paper Mills, Kent; Journals to 4, Kent Road, Gravesend.
- Bhaduri, Prof. K., Kala-Bhavan, Baroda, India.
- Bibby, E. V., Garston Copper Works, Garston, near Liverpool.
- Biekerdike, W. E., Clayton Grange, Wiltsire, near Blackburn.
- Bicket, J. H., The Limes, Cranwich Road, Stamford Hill, N.
- Biggart, J. Wm., 29, Cathcart Street, Greenock, N.B.
- Biggart, Wm. L., Woodbine, Bridge of Weir, N.B.
- Biggs, B., 3, Lawrence Pountney Hill, London, E.C.
- Bihn, G. F., Pennsylvania Salt Manufacturing Co., Philadelphia, U.S.A.
- Billing, H. S., 5, Regent Terrace, Plympton, South Devon.
- Bindschedler, Dr. R., Basle Chemical Works Bindschedler, Basle, Switzerland.
- Binney, H. A., Ravenhead, St. Helens.
- Birch, R. W. Peregrine, 5, Queen Anne's Gate, Westminster, S.W.
- Birch, Wm., Milton Street Ironworks, Lower Broughton, Manchester.
- Bird, Henry, 10, Lockyer Road, Mutley, Plymouth.
- Bird, R., Ellerslie, Roath, Cardiff.
- Birley, R. K., Messrs. Chas. Macintosh & Co., Cambridge Street, Manchester.
- Bischof, Gustav, 4, Hart St., Bloomsbury, London, W.C.
- Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, London, E.
- Bishop, Fred, c/o Linlithgow Oil Co., Ltd., Linlithgow, N.B.
- Bishop, G. A., Gartverrie Fireclay Works, Coatbridge, N.B.
- Black, Wm., Stanrigg, Airdrie, N.B.
- Black, Wm., 12, Romulus Terrace, Gateshead.
- Blackwell, G. G., 26-27, Irwell Chambers West, Fazakerley Street, Liverpool.
- Blagden, W. G., 1, Fenchurch Avenue, London, E.C.
- Blair, John, 18, Old Mill Road, New Hendon, Sunderland.
- Blake, Arthur, Dean House, Redhill, Surrey.
- Blake, C. A., 47, Piccadilly, London, W.
- Blake, Jas., Thames Sugar Refinery, Silvertown, London, E.
- Blakey, A. J., Dudbridge Mills, Stroud, Gloucestershire.
- Blass, Edw., Essen (Ruhr), Germany.
- Bleas, John, c/o Langworthy Bros. and Co., Lim., Greengate Mills, Salford.
- Blenkinsop, W., Garden Wharf, Battersea, London, S.W.
- Bles, A. J. S., 32, Chorlton Street, Manchester.
- Bloede, Victor G., Patuxent and Dillon Streets, Baltimore, Md., U.S.A.

- Bloomer, Fred. J., 15, Broderick Road, Tooting, S.W.  
 Bloomfield, R., Thurnia Factory, via Darbhanga, Tirhoot, India; and (subs.) 4, Seaward Place, Broughty Ferry, N.B.  
 Blount, Bertram, Chemical Laboratory, Broadway, Westminster, S.W.  
 Bloxam, A. G., The Goldsmiths' Institute, New Cross, S.E.  
 Bloxam, W., Popplewell, Royal Naval College, Greenwich, S.E.  
 Blundstone, E. R., Cornwall Lodge, St. James' Road, New Hampton, Middlesex.  
 Blyton, J., 12, Cromford Court, Market Street, Manchester.  
 Boa, Peter, 119, George Street, Edinburgh.  
 Boake, A., Southwood Lawn, Highgate, N.  
 Boake, Edmund J., Southwood Lawn, Highgate, N.  
 Board, J. T., Distillery, Cheese Lane, Bristol.  
 Bond, Louis W., Box 506, Seattle, Wash., U.S.A.  
 Bonn, J. Edwin, High Street, Brading, Isle of Wight.  
 Bookman, S., Pestalozzistrasse, 28, 1, r., Charlottenburg, Berlin.  
 Boor, Leonard G., 1 and 2, Artillery Lane, London, E.C.  
 Booth, F. W., The Gardens, Whittington, near Chesterfield.  
 Booth, Geo., Ark Vale Dyeworks, Middleton, near Manchester.  
 Boothby, Chas., c/o J. L. Wade & Co., Manor House Wharf, Vauxhall, S.W.  
 Borland, John, Etruria, Kilmarnock, N.B.  
 Borland, W. D., Beacon Lodge, Green Street Green, near Dartford, Kent.  
 Bothamley, C. H., Fernleigh, Haines Hill, Taunton, Somerset.  
 Bott, Dr. Wm., Singapore, S.S.  
 Böttinger, H. T., Elberfeld, Germany; and (subs.) c/o Bryce and Rumpff, 20, Booth Street, Manchester.  
 Bottle, Alex., 4, Godwyne Road, Dover.  
 Boulton, H. E., 64, Cannon Street, London, E.C.  
 Boulton, James, Crayford Mills, Stratford, E.

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—Vol. XIII.]

JANUARY 31, 1894.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2 6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond, F.R.S. ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.
E. Rider Cook ....	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S. ....	1891—1892.
Sir John Evans, K.C.B., F.R.S. ....	1892—1893.

## COUNCIL FOR YEAR ENDING JULY, 1894.

**President:** E. C. C. Stanford.

### Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	Dr. W. H. Perkin, F.R.S.
Horace T. Brown, F.R.S.	Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.
H. Brunner.	John Spiller.
Wm. Crowder.	Prof. T. E. Thorpe, F.R.S.
Sir John Evans, K.C.B., F.R.S.	Sir John Turney.
Dr. F. Hurter.	
E. K. Muspratt.	

### Ordinary Members of Council:

R. Forbes Carpenter.	Robert Irvine.
Prof. Frank Clowes, D.Sc.	John Pattinson.
Dr. C. Dreyfus.	Manning Prentice.
Thos. Fairley.	Boverton Redwood.
Prof. G. G. Henderson, D.Sc.	A. Gordon Salamon.
C. C. Hutchinson.	T. Tyrer.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

**General Secretary:** Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## NOTICES.

Notice is hereby given in accordance with Rule 51 of the By-Laws that the Council will propose to the forthcoming Annual Meeting the amendment of the Society's By-Laws as follows:—

1. That *Rule 7* be amended by the deletion of "and" in the first line thereof, and by the addition of the words "and 47" in the same line.

2. That under *Rule 18* the form of nomination of candidates for the Council be amended by transferring the candidate's declaration to the end thereof, and that the words "and by the nominee" be added in the third line after the above-mentioned form after the word "subscriptions."

3. That the proviso at the end of *Rule 22* be deleted.

4. That in *Rule 26* the Nomination Form for candidates for Membership be amended to read as follows:—

"We, the undersigned members of the Society of Chemical Industry, hereby propose  
(*candidate's name in full*) as a fit and proper person to become a member of the Society.

(*For names only of members  
recommending the candidate.*)

"And I, the said candidate for membership, hereby declare that if elected I will do my best to support the Society and will observe its By-Laws.

(Signature) \_\_\_\_\_ (Profession) \_\_\_\_\_

(Address) \_\_\_\_\_ (Date) \_\_\_\_\_

*Extract from By-Laws (Rules 27, 29, and 30).*

5. That *Rule 27* should read as follows:—

"Each member shall pay an annual subscription of twenty-five shillings, due on the 1st January in each year; except that any member may pay a life composition fee of twenty pounds in lieu of an annual subscription. He shall also pay on receipt of notice of election an entrance fee of one guinea in addition to his first year's subscription; except that should a member who has paid an entrance fee resign and subsequently seek re-election the Council may dispense with a further entrance fee."

6. That in the second line of *Rule 28* the words after "and" read as follows:—"issued to the members once every year."

7. That *Rule 29* read as follows:—

"No person shall be entitled to the privileges of membership who has not paid his subscription for the current year. He shall not attend meetings nor vote, nor shall he receive gratuitously the publications of the Society. Should the subscription remain unpaid eight months after it is due, the Secretary shall give the member notice that unless payment be made within four months after the date of such notice, his name will be struck off the register. At the expiry of the said period, if the member should still remain in default, the Council may order his name to be removed from the register, whereupon he shall cease to have any right, privilege, or interest in the Society, and the Council may notify the same in the Journal and recover the arrears of subscription at law."

8. That *Rule 30* read as follows:—

"Any member may withdraw from the Society at the end of any year by giving previous notice to the General Secretary of his intention to withdraw; always provided that such notice to be valid must be accompanied by the payment of all subscriptions, if any, which may be due from him to the Society at the date of the notice. By such notice and payment he shall be released from all further liability as a member."

9. That the following Rule be added after *Rule 53* of the present Rules:—

"All communications between Local Sections and Public Bodies or Societies shall be conducted through or be at the discretion of the Council; and no publication shall be issued by any Section to the general public without the previous consent of the Council."

10. That *Rules 54* and *55* be placed after *Rules 34* and *38* respectively, and that the succeeding Rules be renumbered accordingly."

#### BANKERS' ORDERS.

For the convenience of Members, the Treasurer has arranged with the Bankers of the Society that they shall collect subscriptions from Bankers in town and country; and Members, who have not already done so, are invited to fill up and sign the Banker's Order enclosed with this number of the Journal, which should then be sent to the Honorary Treasurer, Mr. E. Rider Cook, East London Soap Works, Bow, E.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under *Rule 41* of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

#### LIST OF MEMBERS ELECTED 23rd JANUARY 1894.

Anderson, W. Carrick, jr., Mavis Bank, Partick Hill, Glasgow, university assistant.

Barracloagh, T. C., 20 Bucklersbury, London, E.C., engineer.

Briggs, J., Burnett, Vauxhall Soap Works, 6, Blackstock Street, Liverpool, soap manufacturer.

Brunton, J. Dixon, Wire Mill, Musselburgh, N.B., wire manufacturer.

Banting, W. Lightfoot, c/o F. W. Ashton and Co., Hyde, near Manchester, calico printer.

Burgess, Herb. E., 144, Warwick Street, Ecclestone Square, S.W., chemist.

Carswell, Thos. R., Day House, Day Street, Newcastle-on-Tyne, analyst and teacher.

Charlier, Andrew, 107, Breadalbane Terrace, Hill Street, Glasgow, manager and chemist.

Chatard, Dr. T. M., 1410 G. Street, Washington, D.C., U.S.A., chemical engineer.

Cheney, J. P., c/o Cheney Bros., South Manchester, Conn., U.S.A., silk chemist.

Clayton, Robt. H., 762, Rochdale Road, Manchester, chemist.

Crossley, Dr. Arthur W., The Owens College, Manchester, hon. demonstrator in organic chemistry.

Ede, Henry E., c/o Rev. Moore Ede, The Rectory, Gateshead-on-Tyne, analytical chemist.

Fuller, Chas. J. P., Laboratory, L. & Y. Ry. Works, Horwich, near Bolton, analytical chemist.

Gurney, J. Clare, Fabrica Roma, La Union, Prov. de Murcia, Spain, analytical chemist.

Heal, Carlton, Leather Department, Yorkshire College, Leeds, student.

Hett, Stephen J., 25, Percy Street, Liverpool, analytical chemist.

Lockwood, Jos., 263, Argyle Street, Glasgow, artist and patent agent.

McCann, Owen, 158, Tredegar Road, Bow, E., printing ink and varnish maker.

Martin, Alex. M., Douglas Villa, Dunbeth Road, Coatbridge, N.B., analytical chemist.

Martyn, T. Graham, Trevemper Bridge, Newquay, Cornwall, mining engineer and metallurgist.

Miller, J. Carlie, 89, Rumbold Street, Bridgeton, Glasgow, tar distiller.

Pattinson, Dr. H. Salvin, 75, Side, Newcastle-on-Tyne, analytical chemist.

Peden, Jno., jun., Blair Terrace, Greenock, N.B., analytical chemist.

Rodda, Edw. D., 6, Gold Street, Roath, Cardiff, engineer.

Schad, Dr. Philip, 4, Dyar Terrace, Winnington, Northwich, analytical chemist.

Schryver, Dr. S. B., University College, Liverpool, assistant lecturer on chemistry.

Schweitzer, Dr. H., 159, Front Street, New York City, U.S.A., analytical chemist.

Skinner, C. Weeding, Wansfell, Theydon Bois, Essex, manufacturing chemist.

Sonstadt, Edw., Church Fields, Cheshunt, Herts, chemical technologist.

Stevens, Jno. H., The Celluloid Co., Newark, N.J., U.S.A., manufacturing chemist.

Thomas, H. Russell, Broad Plain Soap Works, Bristol, soap manufacturer.

Wade, W. Luvian, 28, West Kensington Gardens, London, W., chemist.

Wareing, Arthur E., Bedford House, Appleton, Widnes, analytical chemist.

White, B. Newport, Manor Hill, Marple, Cheshire, consulting brewer.

Wimpenny, John, c/o Dublin and Wicklow Manure Co., Lim., Wicklow, Ireland, mauager.

### CHANGES OF ADDRESS.

Barrie, D. McL., Journals to c/o Langhaagte G. M. Co., P.O. Box 98, Johannesburg, S.A.R.

Billing, H. S., Journals to 5, Regent Terrace, Plympton, South Devon.

Bowing, John, Journals to Fuel Works, Tilbury, Essex.

Breen, G., Journals to c/o United Alkali Co., Lim., 204, St. Vincent Street, Glasgow.

Brown, J. Henry, 1/o North Wales; c/o Bowman, Thompson, and Co., Lim., Northwich.

Burton, Wm., 1/o The Potteries; Clifton Junction, near Manchester.

Campbell, Arch., 1/o Thornton; 42, Whittaker Road, Upton Park, E.

Coleman, J. B., 1/o University College; Burley House, Carlton, Nottingham.

Collins, C. S. A., Journals to c/o Mrs. Stevens, 56, Elmu Row, Leith Walk, Edinburgh.

Corbett, J., M.P., 1/o Stoke Prior; Impney, Droitwich.

Davis, Herbert J., 1/o Wall Street; 255, West 71st Street, New York, U.S.A.

Dixon, M. T., 1/o Johannesburg; 5, Brandling Park, Newcastle-on-Tyne.

Duffield, Dr. S. P., 1/o Detroit; Dearborn, Wayne Co., Mich., U.S.A.

Duncan, Jas., 1/o Mentone; Maison Ganich, Biarritz, France.

Edgell, G. E., 1/o 5; 3, Queen's Terrace; Gateshead-on-Tyne.

Ekman, C. D., 1/o Italy; Paper Mills, Northfleet, Kent.

Fenwick, Jas., 1/o Huelva; 23, Ronald Street, Glasgow.

Fiebing, J. H., Journals to 644, 28th Street, Milwaukee, Wis., U.S.A.

Fleming, J. Arnold, 1/o Glasgow; Woodland Pottery, Tunstall, Staffs.

Garrett, F. C., 1/o Newcastle; The Polytechnic, Woolwich, S.E.

Girdwood, Dr. G. P., 1/o Beaver Hall Terrace; 82, University Street, Montreal, Canada.

Hawliczek, J., 1/o Queensgate; Claremont Park, Blackpool.

Hulme, Jas., 1/o Hollingworth; Newton Chemical Works, Hyde, Manchester.

Hunt, Bertram, 1/o Glasgow; P. O. Box 1606, Denver, Col., U.S.A.

Hunt, W., Journals to Hampton House, Wednesbury

Hunzinger, A., Journals to Dinting Vale Printworks, Dinting, Derbyshire.

Inglis, R. A., 1/o Arden; Culrain, Bothwell, N.B.

Isaac, T. W. Player, 1/o Marine Parade; 11, Cavendish Place, Brighton.

Johnson, J. Henry, 1/o Lincoln's Inn; Mountains, Tonbridge, Kent.

Kay, Dr. P.; Journals to 196, Heerenstraat, Leiden, Holland.

Kibble, W. Oakes, 1/o Buckhurst Hill; Tavern Street, Stowmarket, Suffolk.

Laurie, A. P., 1/o Cambridge; 49, Beaumont Square, London, E.

Liepmann, Dr. H., 1/o Glasgow; c/o Cracker Creek G. M. Co., Ltd., Eureka, Baker Co., Oregon, U.S.A.

Lunn, C., 1/o Rotterdam; 3, Osborne Road, Antfield, Liverpool.

McBeath, J. W., 1/o West Hartlepool; (Journals) Kimberley, South Africa; and (subscription) c/o H. C. McBeath, Greatham Terrace, West Hartlepool.

McFarlane, J. A.; delete Glasgow address for subscriptions.

McKellar, W. G., Journals to c/o United Alkali Co., Lim., Eglinton Works, Irvine, N.B.

Mansbridge, Wm., Journals to c/o Goodwin Manufacturing Co., St. Louis, Mo., U.S.A.

Marshall, Prof. T. Rymer, 1/o Edinburgh; St. Mungo's College, Glasgow.

Mercer, J. B., 1/o 322; 330, Lower Broughton Road, Manchester.

Miller, Dr. H. von, 1/o Hruschau; Beatrixgasse 32 III., Vienna, Austria.

Miller, Dr. Harry E., 1/o San Francisco; 1264, 14th Street, Oakland, Cal., U.S.A.

Morris, Dr. G. Harris, 1/o Burton; 72, Chancery Lane, London, W.C.

Moss, John, Journals to Wilson Street, New Cross Road, S.E.

Oddie, Jas.; delete London address for subscriptions.

Pettigrew, John, 1/o 18; 6, St. Helen's Place, Bishops-gate, E.C.

Powell, A. Ernest, 1/o Cross Street; 59, Egerton Road, Fallowfield, Manchester.

Prinz, Dr. Otto, 1/o Bavaria; Sesto Fiorentino, Italy.

Ramsden, Edw., 1/o Great Horton; 11, Cecil Avenue, Horton Park, Bradford.

Ray, Wm., 1/o Sale; 33, Sloane Street, Brooks Bar, Manchester.

Raymond, C. W., 1/o Poplar; 65, Clova Road, Forest Gate, E.

Rintoul, Wm., 1/o Poplar, 43, King William Street, Greenwich, S.E.

Russell, D., 1/o Leven; Cadham, Markinch, Fife, N.B.

Sach, Robt.; Journals to c/o Señor César García, Honda, Republic of Colombia, South America.

Schweich, E., 1/o Regent's Park; 47, Victoria Street, Westminster, S.W.

Small, Evan W.; Journals to Sunnyside, West Park, Newport, Mon.

Sykes, E., 1/o Bolton; 111, Victoria Street, Newton, Hyde, Cheshire.

Tetley, C. F., 1/o Headingley; Messrs. Jos. Tetly and Son, The Brewery, Leeds.

Turner, W. Spence, 1/o 225; 227A, Oxford Street, Manchester.

Twynam, T., 1/o Chiswick; Elmhurst, Egham Hill, Surrey.

Voss, H., 1/o Penge Road; 19, Beckenham Road, Beckenham, Kent.

Wadman, W. E.: Journals to 102, Lord Avenue, Bayonne, N.J., U.S.A.

Waterhouse, R., 1, o London; Earncliffe, Beech Hill Road, Sheffield.

White, J. Campbell; all communications to "Overtoun, Lord," 7, West George Street, Glasgow.

### CHANGE OF ADDRESS REQUIRED.

Jarman, G. S., 1, o Croft House, Marsh, Huddersfield.

### Deaths.

Brown, Jas. T., 7, Beaufort Street, Chelsea, S.W.

Button, H., Rainham, Essex.

Eastlake, T. Lloyd, 23, Great George Street, Westminster, S.W.

Miller, Robt., 79, West Nile Street, Glasgow.

Neil, W., 126, Turner's Road, Burdett Road, E.

Sharpley, H., Limber Magna, Ulceby, Lincolnshire.

Upward, W., Albert Road, Widnes.

### ERRATUM.

In the December changes of address, the name of J. Carter Bell was given in error for that of Percy Carter Bell.

## Liverpool Section.

UNIVERSITY COLLEGE, BROWNLOW STREET.

### SESSION 1899.

Feb. 7th:—

Professor E. Divers, F.R.S. "The Manufacture of Calomel in Japan."

Mr. J. Beveridge. "The Manufacture of Straw Pulp."

March 7th:—

Mr. F. H. Tate. "Methods for the Rectification of Vitriol."

Mr. Max Muspratt. "The Quantitative Estimation of Cadmium."

April 4th:—

Mr. J. Henry Brown. "The Treatment of Cupreous Iron Pyrites as carried out at Portuguese Mines."

Meeting held Wednesday, December 6th, 1893.

MR. EUSTACE CAREY IN THE CHAIR.

## THE MANUFACTURE AND INDUSTRIAL VALUE OF ALUMINIUM ALLOYS.

BY J. H. J. DAGGER, F.I.C., F.C.S.

IN the two papers I have had the honour of reading before this Society, and in a paper read before the British Association in 1889, I gave some account of the present day methods for the production of this industrially new metal, and, expressing my views as to its value, based upon an especial experience of the metal in the laboratory, foundry, and workshop, I then stated that "the greatest value of aluminium is as yet in its alloys"; that these words hold true, and that the alloys of aluminium have a value that can hardly be over-estimated, I will endeavour to set forth this evening. Aluminium alloys readily with all the common metals, with one or two exceptions, and with gold, silver, and platinum. These alloys may be conveniently considered as divided into two classes, simple and complex: aluminium alloyed with one metal, or with two or more.

*The Simple Alloys.*—The most important are the copper alloys; these form two series:—Aluminium bronzes with 1 to 11 per cent. of aluminium, and aluminium copper alloys with 90—99 per cent. of aluminium. The intermediate alloys form a series differing widely in colour and other physical characteristics of great scientific interest, but, owing to their crystalline brittle nature, valueless in the arts. The 10 per cent. aluminium bronze is perhaps the best known; it was first prepared by Dr. Percy, of the Royal School of Mines, in 1855, and as early as 1859 a series of experiments were made with it, a mountain gun being cast of it under the direction of the Committee of Artillery of France, and in 1860 further experiments in this direction were made by the Bavarian military authorities, both the French and Bavarian experts reporting that the cost of aluminium bronze was the only thing then prohibiting its use for guns. In his report on the Augsburg artillery trials, Colonel Weber states that the aluminium bronze resisted a pressure of 97,012 lb. per square inch, whilst the tin bronze then used gave only a pressure resistance of 39,601 lb. At that time, pure aluminium was 38s., aluminium 10 per cent. bronze 4s. 11d., and tin bronze 1s. 3d. per lb.

Aluminium bronze is prepared by two methods. 1. By direct reduction of aluminium ore, such as corundum or rich bauxite in presence of metallic copper in the electric furnace; this method I have previously described.\* Since that time, however, the old longitudinal furnace has been replaced by an upright one; the carbon walls now form the negative electrode, the positive being a bundle of carbon rods, plates, or a single carbon cylinder. The positive electrode is coupled to the cable as before, and is capable of being raised or lowered through an opening in the furnace cover; this cover is of iron and is kept cool by the circulation of cold water within it. At the bottom of the furnace is a tap hole closed by a carbon rod. By this method, a rich alloy containing 20 to 30 per cent. of aluminium is obtained, which is checked by analysis and standardised by the addition of copper. The following is a typical analysis of this crude bronze or "furnace product":—

Copper .....	71.517 (by difference)
Aluminium .....	20.147
Silicon .....	4.116
Iron .....	4.220

By using prepared alumina almost free from silica and iron, a very pure alloy can be obtained. 2. The better and more general method is by direct mixture of the metals in the crucible. The process is as follows:—The copper is first melted, and then the necessary quantity of aluminium added in portions, using a perforated ladle to facilitate mixture. For the first addition of aluminium there will be great evolution of heat rising to incandescence; this gradually

\* This Journal, September 1889.

diminishes as the remainder of the aluminium is added, care being taken to prevent overheating of the ladle and tools used during the mixing. The tools and ladle must be perfectly clean, free from scale, and it is best to change the hot rod for a fresh one. Blacklead pots must be used, and the greatest care taken to prevent the molten metal coming into contact with sand or siliceous matter, for aluminium readily reduces silicon from its compounds. Fluxes must not be used, but carbon may be placed over the molten metal if thought needful. Much trouble and failure to obtain good results in the foundry has arisen from using clay pots, neglecting these precautions, and using too high a mixing temperature. If a bronze requires to be as free as possible from silicon, crucibles lined with carbon must be used. This bronze is of a bright golden colour, its density is 7.69, it gives fine castings, is malleable, but requires frequent annealing if worked in the cold. It works well under the tool and takes a high polish.

The alloy containing 11 per cent. of aluminium is higher in tensile, transverse, and torsional strength; a small round cast bar tested by the Leeds Forge Co. Ltd. gave T.S. 57.27 tons, or 128,000 lb. per square inch.

This alloy is exceedingly hard and trying to the tools, and in it we have reached the highest useful limit of aluminium in low per cent. alloys. The alloys containing less than 10 per cent. aluminium are all of very great value. The tensile, transverse, and torsional strengths and resistance to compression decreases as the aluminium is lowered; this is accompanied by a proportional increase of elongation. Their colour varies from pale yellow to red gold; they can be readily cast, rolled, and drawn in the cold, and can be worked easily at bright red heat. Sheets, rods, bars, and wire are rolled at a bright heat and finished cold. The effect of working and rolling is shown in some of the tests given below. The fracture of the 10 and 11 per cent. bronzes are crystalline, that of the others fibrous.

You will notice that they far surpass ordinary bronze and gun-metals, and compare favourably even with steel.

The destructive effect of heat on gun metal (tin bronze) is one of the most serious objections to the use of that alloy. The aluminium bronzes, on the contrary, show no sign of liquation on melting, and there is no separation of the metals on slow cooling, and so sounder castings can be

TABLE I.  
ALUMINIUM BRONZE.—AVERAGE TESTS.

Aluminium Per Cent.	T.S. in Lbs. per Square Inch.	Elongation Per Cent.
10	69—100,000	4—14
8½	55—65,000	12—28
7½	35—45,000	8—32
5—5½	35—40,000	30—40
2	30,000	40—50
1	20,000	10—55
11	50—100,000	0—87.0

made from them. They retain their tenacity through a high range of temperature. Professor Unwin obtained the following result with a bar of this bronze:—

Specimen.	Heated to F.	T.S. in Lbs. per Sq. Inch.	Per Cent. of Elongation.
10 per cent. aluminium	350°	86,240	26.3
Bronze, rolled bar.....	500°	81,828	27.5

Other temperature tests made at Cowles' Company's laboratory are given in my paper in the Journal for 1889.

*Complex Alloys of Aluminium.*—Of these the most important contain zinc and copper with varying proportions of aluminium, forming the so-called aluminium bronzes. The composition of these alloys varies from 1 to 6 per cent. of aluminium combined with 12 to 43 per cent. of zinc, the remaining constituent being copper.

The following tables indicate the composition and mechanical properties of this class of alloy.

# ALUMINIUM BRASS.

Notes.	Composition of Alloy.				T.S. per Square Inch.		Elongation per Cent.	Authority.

The percentage of aluminium in aluminium brass depends upon the amount of zinc present, since the aluminium must decrease in quantity with an increase of zinc, otherwise the alloy will become brittle and unworkable. With 40 per cent. of zinc the aluminium should not exceed 1 per cent., with 30 per cent. of zinc, 2 per cent. of aluminium, with 11 per cent. of zinc 6 per cent. of aluminium may be added. This alloy is best made by melting 10 per cent. aluminium bronze with the quantity of copper required, and when the ingots are melted and thoroughly mixed in the crucible, adding the zinc. The metal is left in the furnace until small test bars taken from it and broken show the required tensile strength and ductility; it is then ready for pouring.

Other alloys of this class contain small percentages of manganese and tin, usually not exceeding 0.5 of either metal.

The following is an example of this alloy

Specimen.	Composition.	Tensile Strength.	Elongation.
Cast bar of aluminium-manganese-bronze.	Aluminium ... 2.000	85,300 lb.	14.25 per cent.

Metal for rolling into sheets and rods has often 0·5 per cent. of lead added to the alloy. Aluminium brass can be forged and worked readily under the hammer; the working heat must be lowered with the decrease in the percentage of aluminium. The 3 per cent. aluminium alloy with 33 per cent. of zinc can be worked at a dark red heat, contrasting in this respect with common brass. These alloys all give sharp, clean, tough castings, and from their high tensile and

transverse strength and their corrosion resistance they ought to be most valuable to the marine and mechanical engineer. They have already been tried as a material for propeller blades, and, judging from results obtained, ought to displace other bronzes in this class of work.

The following are comparative tests of transverse strength:—

COMPARATIVE TESTS OF TRANSVERSE STRENGTH.

*The Casting of Aluminium Bronze and Brass.*—The following are the melting points of aluminium bronze, as compared with the pure metal and other alloys and metals:—

Metal or Alloy.	Melting Point.
	° F.
Aluminium.....	1,300
Copper.....	1,900
Iron.....	Cast, above 2,780
	Wrought, above 1,000
Steel.....	1,000
Steel bronze (gun bronze).....	1,100—1,200
Aluminium bronze (aluminium brass).....	1,000—1,700

In making castings from aluminium bronze and brass the difficulties, as in other metals and alloys, arise from oxidation, contraction, shrinkage, and the enclosing of air bubbles, but no gases are produced during the melting of the alloy, and there is no trouble from the occlusion of gases, as in the case of other metals.

The liquid bronze on exposure to air is instantly covered with a thin film of oxide, which protects the under metal from any further oxidation; in pouring, care must be taken to prevent any of this film getting into the casting; this is best done by making a "pouring gate" or receiver, into which the metal is first poured.

The molten bronze is kept back until the impurities have risen to the surface, when the plug is withdrawn and the clean metal enters the mould. Instead of a "pouring gate" a secondary pot or ladle can be used.

Contraction must be guarded against by having cores of a yielding character, avoiding as far as possible core-rods or irons; coarse sand mixed with rosin, which softens on heating, makes a good core. To diminish shrinkage the gates must be made as large as possible and the pouring done quickly, and at no higher temperature than is necessary to ensure a good casting.

CORROSION RESISTANCE OF ALUMINIUM ALLOYS. NEUBAUER LABORATORY TESTS.

Specimen.	Weight in Grams.	Surface.	Reagent.	Temperature.	Time of Exposure.	Loss Per Cent.
2·4 per cent. aluminium bronze.....	9·346	50 cm. sq.	5 per cent. acetic acid.	Ordinary.	504 hours.	0·440
10 per cent. free from silicon.....	..	Equal surfaces.	5 per cent. acetic acid and 3 per cent. solution of common salt.	80°—90° C.	14 "	1·0
10 per cent. aluminium bronze with 2·8 per cent. of silicon.*					14 "	2·1
Aluminium brass, 3·5 per cent. aluminium.						4·4

\* A specimen tested in the Milton Laboratory indicates the influence of silicon on corrosion resistance. A polished bar of 10 per cent. bronze, normal colour, strength, and elongation, gave following result:—

17·432	22 cm. sq.	Pure conc. H <sub>2</sub> SO <sub>4</sub>	6°—11° C.	336 hours.	0·401
--------	------------	---	-----------	------------	-------

The action of the sulphuric acid developed a dark band in form of a spiral round the bar; this showed minute corrosion pits under lens, which gave off sulphuretted hydrogen; the corrosion was apparently confined altogether to this dark patch. Silicon alloyed with iron is often 1·5 as a black insoluble powder on dissolving the bronze in aqua regia.

Langley's patent.	Langley's patent.		26.7	60,000

**High per cent. Aluminium Alloys.**—Very many experiments have been made to increase the tensile strength and hardness of aluminium, and with considerable success, though at some slight sacrifice of lightness and corrosion resistance. For ordinary foundry and workshop castings the addition of 1-6 per cent. of copper is the most ready and serviceable method. The mechanical tests of such an alloy are shown in the table. The addition of only 2 per cent. of copper increases the tensile strength of rolled aluminium from 12 to 19½ tons per sq. inch, while 6 per cent. doubles it; a further addition of copper increases both the hardness and brittleness, but the alloys containing between 12 and 90 per cent. of aluminium are industrially valueless.

**The Alloys with Tin.**—From my own experiments I find the addition of not more than 2½ per cent. of tin to aluminium gives a hard serviceable alloy with a slightly improved colour. Richer alloys are crystalline and brittle.

(Samples containing 2 per cent. and 50 per cent. of tin were exhibited.)

**The Alloys with Titanium.**—For information as to these alloys I am indebted to Dr. J. W. Richards, Professor of Metallurgy at Letrigh University, U.S.A. The alloy containing 2 to 3 per cent. (Langley's patent) gives a tensile strength of 40,000 to 60,000 lb. per sq. inch in forgings; this alloy is especially useful for horse shoes, stirrups, bits, and small, strong fittings.

**Alloys with Nickel and Zinc.**—The addition of nickel lowers the melting point, and increases the hardness and elasticity, if added in quantities not exceeding 2 per cent.; above this figure the alloy is brittle and useless.

With zinc, aluminium forms hard, close-grained, brittle alloys having a lower melting point than that of the constituent metals. A small ingot containing 10 per cent. of aluminium and 90 per cent. of zinc is among the samples on the table. A very useful alloy contains 3 per cent. of German silver. It has double the tensile strength of aluminium itself. Professor Richards had samples of it tested at Watertown Arsenal, and while not quite equal to the titanium alloy in tensile strength, its elasticity was greater; this alloy is suitable for knives, spatulas, paper cutters, spectacle frames, and all uses where elasticity is essential.

**Alloys with Silver.**—Aluminium alloys readily with silver in all proportions. With up to 6 per cent. of silver the elasticity and hardness increase, beyond this proportion the brittleness increases, but alloys containing up to 30 per cent. of silver are serviceable. These alloys, owing to their hardness, lightness, bright lustre, and permanency, are excellent for art work.

**Chromium Alloys.**—For a description of these alloys I have to thank Mr. H. N. Yates. He finds from experiment that the addition of chromium increases the hardness, while it reduces the strength and ductility of the aluminium.

**Cadmium Alloys.**—Aluminium is said to form malleable fusible alloys with cadmium in all proportions, but I have not been able to verify this statement.

**Alloys with Iron, &c.** Aluminium alloys readily with iron in all proportions. Aluminium containing more than 1 to 2 per cent. of iron is hard and brittle; with 8 per cent. the alloy crystallises in needles.

Iron containing 15 to 16 per cent. of aluminium cast in the chill is marked by the file with difficulty; the fracture is fine and crystalline.

An alloy of steel containing 1 per cent. of manganese with 7 per cent. of aluminium will just scratch glass. Although aluminium is said by some writers to diminish hardness in iron, used in even small proportions, it is to my mind sufficiently clear that this depends entirely upon the change in the state of the contained carbon.

Above 5 per cent. of aluminium rapidly destroys the magnetic properties of iron, and some time ago experiments were carried out in the Milton laboratory to determine whether this phenomenon would furnish any clue to the percentage of aluminium present in iron alloys, but the results were not precise enough for quantitative indications.

**The Use of Aluminium in Melting and Casting other Metals.**—Very large quantities of the aluminium produced go for use in iron and steel founding in this country, and Professor Richards and Mr. Yates report that there is hardly a steel melter in the States that tries to do without it, and that they are the largest users. This brings me to the consideration of the influence of minute quantities of aluminium on other metals. The percentage used is so small that such mixtures cannot be truly termed alloys. The action of aluminium is probably twofold: chemical and physical. Chemical, owing to its affinity for oxygen and the stable character of the oxide when formed; physical, causing changes in the structure of the alloy, crystalline to non crystalline.

The effect of aluminium is due to—

First, Its action on the combined carbon, changing it to the graphitoidal form; the carbon is apparently liberated at the moment of solidifying and uniformly. 0.25 per cent. of aluminium added to white iron renders it perceptibly darker in colour, 0.5 per cent. darker still, and 0.75 per cent. renders it grey with no sign of white. Up to 4 per cent. the effect is similar; the castings are softer and greyer as the aluminium increases.

Secondly, Its action on the dissolved oxides of iron and silicon. These are reduced with the formation of alumina, iron, and free silicon.

Thirdly, Decomposition of gaseous and solid compounds of carbon with oxygen and hydrogen entangled in the molten metal. This is why aluminium is so valuable in steel casting. Some experiments carried out by Professor Langley, of Pittsburg, explains this action clearly. Blow holes in steel are due to non-oxidising occluded gases, hydrogen, carbonic oxide, and nitrogen separating, under a pressure of many atmospheres, from steel just before solidification. It has been proved by repeated experiments that aluminium readily decomposes, carbonic oxide below steel melting heat, forming alumina and free carbon. Professor Langley confirmed this by blowing 40 gallons of pure carbonic oxide through a crucible of molten steel containing aluminium, and obtained an increase of 35 per cent. on the carbon present before passing the gas. The quantities of aluminium used vary with the quality of the steel. For open hearth metal with less than 0.5 per cent. of carbon, 5 to 10 oz. per ton. For steel over 0.5 per cent. of carbon, aluminium must be used cautiously, the quantity usually being 4 to 8 oz. per ton.

These quantities, you will notice, are very minute; 4 oz. per ton being 0.0125 per cent., 16 oz. would be 0.05 per cent. Professor Richards and Mr. A. E. Hunt have patented an alloy made by adding 10 to 20 per cent. of aluminium to ferro-manganese. The addition of the aluminium causes a separation of carbon, and an alloy with less carbon than ordinary ferro-manganese is obtained, admitting of melting softer steel with down to 0.05 per cent. of carbon. As might be expected from its influence on iron and steel, aluminium is useful in the preparation of other metals. It is much used by American galvanisers and brass founders for adding to molten zinc; its action is to reduce the oxide disseminated through the bath. Its effect on the galvanised sheets is at once perceptible. The amount used

is 0.005 to 0.010 per cent. of aluminium, usually in the form of the 4 per cent. aluminium alloy of zinc; one firm in the United States puts 2,000 tons of aluminium zinc on the market yearly. The process is patented in this country. A small quantity added to copper, 0.05 to 0.5 per cent., decomposes entangled oxides and enables sounder and more ductile castings and ingots to be produced without hardening the metal or affecting its electrical conductivity.

In conclusion I would say that the true value of aluminium is not yet known as it ought to be to those engaged in the metallurgical industries of this country, and in its use and applications we are behind the Continent and the United States. In the arsenals, shipbuilding yards, machine shops, and factories of France, Germany, Switzerland, Italy, Denmark, Russia, and the United States, aluminium and its alloys are taking the place of the older tin, zinc, and copper alloys, of cast iron, and in some cases that of steel itself.

I have to express my thanks to Professor Richards and Mr. H. N. Yates for communication of facts as to experiments and use of the metal in the United States; to the Cowles Syndicate Co. for specimens of alloys; to Messrs. Blackwell for specimens of bauxite, to Mr. Lloyd Barnes, of the Liverpool School of Science, for a test of the electrical conductivity of aluminium; to Dr. Bailey for assistance in preparation of the diagrams; and to Mr. C. Boundy for the use of his metallurgical laboratory.

#### DISCUSSION.

Mr. W. P. THOMPSON asked if Mr. Dagger had seen any purple alloys of aluminium, and what was his knowledge with regard to them.

Dr. HURTER remarked that what had struck him very much was the considerable increase in the strength of the metals obtained by adding trifling quantities of aluminium. Taking, for instance, a cast with 3 per cent. of aluminium with 33 per cent. of zinc, there would be 64 of copper. If they divided the several weights by the molecular weights they would find on 0.11 molecules aluminium about 1.6 atoms of other metals. That would be on one atom of aluminium about 15 of copper and zinc. But if they considered that as a cube with so many molecules in it, they would find that on the linear dimensions there would be 1 of aluminium to 3 of the other metal. It struck him that, looking only at the percentages, it did not give one a just idea of the amount of aluminium present. He was pleased that Mr. Dagger brought forward those papers from time to time. He was lately in London, and a gentleman undertook to show him a few experiments, and he was surprised to learn a good many things from them. He had been shown the enormous affinity which aluminium had for sulphur, a thing which one did not altogether realise. It would take sulphur away from nearly every other metal. Aluminium sulphide would be a boon in the laboratory, if only cheap enough, for the preparation of sulphuretted hydrogen. One only needs to pour water upon it when an abundant stream of sulphuretted hydrogen is given off. Aluminium had many properties which rendered it valuable to the chemist, and, comparatively speaking, it was still an unknown substance, and would, no doubt, play an important part in metallurgy.

Professor CAMPBELL BROWN said the subject was full of interest, but there was one alloy mentioned about which he would like more information. Could Mr. Dagger give them any information of how 2 per cent. of titanium was alloyed with aluminium?

The CHAIRMAN said they were all very much struck with the progress made in the metallurgy of aluminium and the immense variety of uses to which it and its alloys could be put. What would a casting of aluminium brass cost per lb. or per cwt. as compared with other alloys of equal tensile strength, or with the best alloy that was known? Mr. Dagger had mentioned screws for steamers; and, assuming the aluminium brass to be very much stronger than another material, a screw, although made of the more expensive alloy, might be really cheaper per lb. or cwt. than the best

made of some other metal. He would also ask what was the present price of aluminium, and what prospect Mr. Dagger thought there was of a reduction of cost?

Mr. A. E. FLETCHER asked where aluminium was produced in the largest quantities.

Mr. DAGGER, in reply, said he was sorry he had not seen any purple alloys of gold and aluminium, but Professor Roberts Austen's description of it was exceedingly interesting, and it made them think how very little they really knew as to the true nature of alloys. Regarding Dr. Hurter's questions, he could not remember with any accuracy the tensile strength of pure copper as compared with aluminium. The figures, however, were given in his last paper, and published in the Journal (this Journal, 1892, 125). Dr. Hurter had compared bulk with per cent., and looking at it that way, it was not so startling after all, because, weight for weight, they would use almost three times the amount of aluminium as they would of copper. The reducing properties of aluminium led one to suppose it would be useful to the chemist in laboratory work, and a great deal had to be done in that direction, as there was plenty of scope for chemists to try how far it would replace the metals that were at present used. Aluminium did not alloy with lead. He had before him a sample that he had made—a very carefully prepared alloy of 50 per cent. tin and lead. It was carefully mixed in the casting, and he had no doubt at all that the tin and lead were thoroughly alloyed together. He then added 50 per cent. of aluminium to that mixture, taking the same precautions, and poured it into a mould, and the aluminium separated the lead from the tin; the two layers could be very distinctly seen. Such a property would render it very useful in the separation of silver from lead. Professor Campbell Brown had raised the question of titanium in alloys. He had not seen that alloy, but understood that it was prepared by reducing titanous oxide with alumina in the furnace. By that means a rich alloy was obtained. Regarding the cost of aluminium alloys, he was sorry to say that was a question he could not answer right off, having no figures with him. The present price of aluminium had not been reduced since he read his last paper nearly two years ago. It remained practically at about 2s. per lb. in ingots of 98.7, or say 99 per cent. in a ton lot. In reply to Mr. Fletcher, the largest factory was undoubtedly that of the Cowles' Company in Lockport, N.Y., U.S.A. Next came the Neuhausen Company, in Switzerland.

SESSION 1893-94.

Feb. 2nd, 1894:—

Mr. Wm. Thomson, F.R.S.E. "The Protection of Metallic Iron from Corrosion."  
Mr. J. Carter Bell. "Notes on the Fertilisers and Feeding Stuffs Act, 1883."

Meeting held Friday, January 5th, 1894.

DR. CHARLES DREYFUS IN THE CHAIR.

### THE MANCHESTER SHIP CANAL.

The CHAIRMAN referred to the importance of the opening of the Ship Canal in its bearing on the chemical trades, and submitted a motion congratulating the directors and shareholders of the Canal Company on the completion of the canal, and wishing success to the undertaking.

The motion was seconded by Mr. Peter Hart and adopted.

Mr. HARRY GRIMSHAW, in supporting the resolution, said, that in fixing the rates for the carriage of chemicals, there seemed to be an amount of uncertainty and ignorance, which ought not to exist amongst railway companies and other carriers. They failed to realise the magnitude of the chemical industries of this country. The quantity of iron ore, sulphur, and the various forms of alkali and other heavy chemicals that came into this district, would run into hundreds of thousands of tons per annum, and it behoved the members of the Society to impress upon the Ship Canal Company and the carriers on the canal the magnitude of the trade, and the importance of the rates for freight being reduced, in order to induce a greater development of the trade in the district.

The CHAIRMAN stated that the matter was already under the consideration of the chemical section of the Manchester Chamber of Commerce, but possibly good might be done by the appointment of a committee to take action on behalf of the Society, and thereby strengthen the hands of the Chamber of Commerce. Liverpool shipowners looked upon chemicals with great disfavour, and this placed this country at a very great disadvantage as compared with other countries. There was no difficulty whatever in shipping any kind of chemicals from such places as Antwerp, Rotterdam, and Havre, or Hamburg, where the charges were not so prohibitive as they were at Liverpool or any place on the east coast. This was mainly owing to the ignorance which prevailed amongst British shippers as to the name and nature of certain chemicals, for the moment one called goods chemicals the Liverpool shippers were frightened. Copperas, for instance, was charged differently from sulphate of iron, which was exactly the same thing. He hoped they would succeed in getting facilities in Manchester such as they had not been able to obtain from Liverpool.

It was agreed to postpone to a future meeting any action in the direction suggested by the Chairman.

### ON THE VULCANISATION OF INDIA-RUBBER.

BY CARL OTTO WEBER, PH.D., F.C.S.

THE chemical nature of india-rubber is very little better known to-day than about 60 years ago, when Gregory\* first examined the products of the dry distillation of this remarkable substance, and found them to consist of a mixture of hydrocarbons boiling between  $-18^{\circ}\text{C}$ . and  $360^{\circ}\text{C}$ . These experiments were repeated later on by Dalton,† Himly,‡ Williams,§ and subsequently by Bouchardat|| with the result that these hydrocarbons were found to belong to the class of the terpenes or polyterpenes. The most important feature of these investigations, no doubt, was the discovery of isoprene  $\text{C}_5\text{H}_8$  (hemiterpene), and the observation that the greater part of the mixture of hydrocarbons obtained, consists of a hydrocarbon, boiling

between  $168^{\circ}\text{C}$ . and  $176^{\circ}\text{C}$ ., and which was found to be identical with di-isoprene or dipentene, a terpene very closely related to citrene.

At present isoprene must be considered the most interesting of the products of the dry distillation of india-rubber. Bouchardat\* observed that by heating it in sealed tubes to about  $300^{\circ}\text{C}$ ., or by treating it with fuming hydrochloric acid it could be reconverted into india-rubber. Tilden† obtained isoprene by distilling turpentine through porcelain tubes at a dull red heat, and discovered 'the poorly' that this compound, on standing, spontaneously polymerises into india-rubber. I am in a position to confirm this observation with respect to isoprene obtained from india-rubber by dry distillation. About 300 grms. of this substance were found after nine months standing to be converted into a very viscid, treacly mass, from which by treatment with methyl alcohol, a solid spongy substance of almost white colour could be separated. This substance, after drying, was of a light-brown colour, and in all respects identical with india-rubber. The methyl alcohol contained about 82 grms. of a thick oil, boiling at about  $215^{\circ}\text{C}$ ., and combining with bromine with formation of a tetrabromide. The weight of india-rubber thus obtained was 211 grms.

Whether in the future we shall succeed to manufacture india-rubber artificially by means of isoprene appears very doubtful as yet. The manufacture of cheap isoprene is certainly an exceedingly difficult task to start with, and on the other hand we have not succeeded so far to completely polymerise it into india-rubber. The by-products of this polymerisation consist of dipentene and polyterpenes, which will always remain comparatively worthless, there being any amount of cheap natural terpenes. At the present time the constitution of isoprene itself is very doubtful. We only know that it contains two ethylene bonds, and for that reason must be a derivative either of allene,  $\text{CH}_2=\text{C}=\text{CH}_2$ , or of vinyl ethylene,  $\text{CH}_2=\text{CH}-\text{HC}=\text{CH}_2$ . Also dipentene contains these two ethylene bonds as is proved by its behaviour against hydrochloric acid, or hydrochloric acid and nitrosyl chloride. Isoprene very easily polymerises into dipentene, and as both these bodies contain two ethylene bonds it is evident that the polymerisation is effected by the resolution of one ethylene bond in each of two molecules of isoprene. Isoprene is, however, able to form a number of higher polymerisation products, of which  $\text{C}_{10}\text{H}_{16}$  and  $\text{C}_{15}\text{H}_{24}$  have been known for some considerable time. The oil I obtained besides india-rubber by the spontaneous polymerisation of isoprene contains about 20 per cent. of dipentene, the rest is a mixture of two substances which so far I failed to separate.§ The estimation of the depression of the freezing point in Beckmann's apparatus strongly indicates this mixture to consist of condensation products of the formula  $\text{C}_{33}\text{H}_{56}$  and  $\text{C}_{40}\text{H}_{64}$ . All these condensation products of isoprene are terpenes or polyterpenes, and the fact that the results of the analysis of india-rubber leads to the empirical formula  $\text{C}_{10}\text{H}_{16}$ , which is that of the terpenes might induce us to pronounce also india-rubber a terpene, or possibly a polyterpene  $(\text{C}_{10}\text{H}_{16})_n$ . Gladstone and Hibbert|| showed that for  $\text{C}_{10}\text{H}_{16}$  india-rubber contains three pairs of carbon atoms doubly linked, and this seems to be confirmed by the existence of a chlorinated derivative  $\text{C}_{10}\text{H}_{14}\text{Cl}_8$ , which corresponds to an addition product  $\text{C}_{10}\text{H}_{12}\text{Cl}_6$ . But terpenes with three ethylene bonds are quite unknown at present, so that unless further evidence be adduced we are scarcely justified to describe india-rubber as a terpene. The above mentioned facts leave very little doubt that the constitution of india-rubber differs very essentially from that of the terpenes and polyterpenes as at present understood. What we know with certainty is the formation of india-rubber from isoprene by polymerisation, and we further know that the molecular weight of it is much higher than  $\text{C}_{10}\text{H}_{16}$ . Under these circumstances it appears very much preferable to describe india-rubber as a polyterpene  $(\text{C}_{10}\text{H}_{16})_n$ . We shall have to bear in mind at the same time that india-rubber

§ Fractional distillation does not avail.

J. C. S., 1888, 679.

is an unsaturated hydrocarbon, a fact which must find expression throughout in the chemical behaviour of india-rubber, and which must be taken into consideration in the chemical influences we subject it to.

The chemical treatment of india-rubber in the manufacture of india-rubber articles is very limited at present and consists exclusively in the treatment known as vulcanisation, which is effected by subjecting the india-rubber either to the action of sulphur at temperatures above the melting point of sulphur, or with chloride of sulphur in the cold.\* The chemical reaction taking place in these treatments has so far scarcely been investigated, still less satisfactorily explained. The authors of the various papers on india-rubber express themselves all with more or less reserve on this point, describing vulcanisation as an "absorption" of sulphur by the india-rubber without explaining the meaning of this term. They are almost unanimous in stating that india-rubber "absorbs" about 2 per cent. of sulphur, leaving however the nature of this absorption undecided. Much more unsatisfactory even are the terms in which the nature of the vulcanisation with chloride of sulphur is described. On the one hand we are told that this treatment also results in an absorption of sulphur by the india-rubber, while on the other hand we are assured that the vulcanising action of the chloride of sulphur is due to its chlorine exclusively, one author going so far as to say chloride of sulphur was merely chlorine in a diluted form. As far as these conflicting assertions are supported by experimental proofs they are certainly deserving consideration. Unfortunately the proofs adduced in either case are, as we shall see presently, of a very unsatisfactory description. Moreover, the chemical reactions which are supposed to take place in these vulcanisation processes are of such an extraordinary kind that they are utterly irreconcilable with each other and still more so with the well-established laws and facts of organic chemistry. I cannot illustrate this better than by giving a selection of extracts from the various papers and other publications bearing upon this subject.

In the first instance the unanimity with which the vulcanisation process is described as a substitution process is greatly surprising in view of the fact that the hydrogen which is being substituted, as far as those authors account for it at all, generally behaves in a manner which is utterly at variance with all we know about substitution processes in organic compounds. With regard to the vulcanisation with sulphur Burghardt† says that "it consists in all probability in the alteration of the caoutchouc resin through the production in it of a 'sulpho-compound,' a certain amount of hydrogen in the caoutchouc being replaced by sulphur."

Burghardt evidently entirely overlooks the fact that in this case sulphuretted hydrogen would be evolved. As a matter of fact whether we vulcanise with sulphur on a small or on the large scale, not a trace of sulphuretted hydrogen, still less hydrogen is given off. Terry‡ also considers vulcanisation a substitution process, accompanied by evolution of sulphuretted hydrogen, but in which manner and under which circumstances he observed the appearance of this gas is not stated. Peculiarly his own is his view of the function of lead oxide in the vulcanisation process. This oxide is added to take up the excess of sulphur which is necessary in the vulcanisation with sulphur and which would prove very detrimental to the durability of the vulcanised articles if remained in the free state in the rubber. Terry§ remarks that no other metallic oxide can replace the oxide of lead for this purpose, and then goes on to say: "Owing to the formation heat of most of the metallic sulphides being above the melting point of sulphur, the sulphide of lead may be taken as the only one formed during ordinary vulcanising processes."

I have not been able yet to fathom the meaning of this sentence and came in the meantime to the conclusion that

\* I am well aware that it has been suggested to vulcanise india-rubber with vaporised chloride of sulphur, *etc.* at higher temperatures, and this process was indeed at one time, especially in America, largely used. But the characteristic property of chloride of sulphur as a vulcaniser consists in its capability to exert its full effect in the cold, even when strongly diluted with indifferent solvents, such as carbon bisulphide, benzene or the light petroleum hydrocarbons.

‡ Terry, *this Journ.* 1892, 970-974.

§ *Loc. cit.*

Terry has never grasped the meaning of the term formation heat, but seems to consider it as a quality comparable with temperature.

The statements given above contain the whole of our present knowledge of the so-called dry vulcanisation process with sulphur. Our present notions regarding the so-called cold vulcanisation process with chloride of sulphur are, if possible, in even a greater state of confusion. Fawsitt\* maintains that vulcanisation in this case consists in the substitution of sulphur for hydrogen, which latter, according to him, escapes as a gas. What happens to the chlorine of the chloride of sulphur is left to the imagination of the reader. Burghardt† in the main adopts Fawsitt's explanation, but he deals in a more rational manner with the chlorine, which he says is given off in the form of hydrochloric acid. Diametrically opposed to these statements is Thomson, who gives it as his opinion‡ that the vulcanising action of chloride of sulphur is due to the chlorine and not to the sulphur of this compound. He asserts that india-rubber vulcanised with chloride of sulphur contains only minute quantities of sulphur as an impurity, but large quantities of combined chlorine and that the same is the case with the oils converted into india-rubber substitute by means of chloride of sulphur. Thomson gives us no information, whether he tried to vulcanise india-rubber with chlorine alone, or whether he obtained india-rubber substitute by treating suitable fatty oils with chlorine. Thomson's results were considered rather startling when first published, but I think his analytical method by which he obtained them is more startling still, and I consider it a matter of great surprise that it never has been challenged. This method consists in fusing the vulcanised rubber or rubber substitute, as the case might be, with caustic potash, dissolving the melt in water, oxidising the "lower sulphur compounds" with peroxide of hydrogen, and precipitating the sulphuric acid with barium chloride. It is a matter of surprise that by means of this method Thomson should have found any sulphur at all in these compounds. At any rate, before applying it to the analysis of these unknown compounds, its suitability for the purpose ought to have been tested on other sulphuretted hydrocarbons of known composition. After this neither the method, nor the startling results it furnished, would ever have got into print. Thomson's view respecting vulcanisation with chloride of sulphur is evidently shared by Terry, on grounds about as remarkable as Thomson's analytical method. Terry expresses himself in the following manner‡:

"With regard to the action of this body (chloride of sulphur), I think there can be no doubt that it is due to the chlorine, and that although some sulphur must necessarily be absorbed at the same time by the rubber, yet that this latter does not play any part in the reaction. Sulphur in the cold has no effect on rubber, and chloride of sulphur must be looked upon as merely chlorine in a diluted form. The action of chlorine in whatever form applied may be measured by the amount of hydrochloric acid produced."

From this we should have to conclude, that since free sulphur in the cold has no action upon rubber, the sulphur of the chloride of sulphur can have no vulcanising action, this vulcaniser being even effective in the cold. A criticism of this argument would be a mere waste of time: the great chemical energy and activity even the most inert elements acquire in many of their combinations is a subject which is treated of in every elementary text book of chemistry. From the last part of the above quoted sentence from Terry's paper it is evident that he also considers the chloride of sulphur vulcanisation a substitution process. Accordingly of one molecule of chloride of sulphur (135 parts) used for vulcanisation only one atom of chlorine (35.5 parts) could remain in the rubber. It is difficult to understand why Terry omitted to ascertain the correctness of his views by estimating experimentally, at least the amount of chlorine combining with rubber from a definite weight of sulphur chloride.

No more fortunate is Terry in his explanation of the action of Fawsitt's new vulcanising agent antimony iodide.

\* *This Journ.* 1886, 638.

† *Loc. cit.*

‡ *Industries*, 9339.

He writes\*—

"As far as I have gone into the matter myself I think that some substitution of hydrogen by iodine certainly does take place" and further on.

"The formation of hydriodic acid cannot be taken as proof that substitution of hydrogen in the rubber has taken place, because hydrogen would be liberated by the action of sulphur present."

From this we must assume that iodine can substitute hydrogen in organic compounds with evolution of hydriodic acid, and further, that sulphur can be substituted for hydrogen, the latter simply being set free. These lines are in complete opposition to our entire knowledge on substitution.

The above quotations are a summary of all that chemical literature contains on the subject of the vulcanisation of india-rubber, and after critical examination, we can only come to the conclusion, that neither the vulcanisation with sulphur, nor that with chloride of sulphur are in the least understood. Even such a simple question as that regarding the minimum quantity of sulphur required for vulcanisation, or the equally simple one whether the vulcanising action of chloride of sulphur is due to the sulphur or to the chlorine, are still objects of controversy. The work on which I am going to report to you to-night has been undertaken with a view to arrive at a definite settlement of these points and at the same time to clear up the chemical mechanism of the vulcanisation processes in general. Historically, the vulcanisation with sulphur preceded the vulcanisation with chloride of sulphur. Notwithstanding this, I first took up the investigation of the last named process, for the only reason that in this last case the vulcanisation is effected under conditions which are much more easily kept under control than is the case with the first process.

#### 1.—Vulcanisation with Chloride of Sulphur.

The action of chloride of sulphur upon hydrocarbons has been studied very little. Whether it is at all capable to react with saturated hydrocarbons is doubtful, and the chemical literature affords no information on this point. But, on the other hand, there are a few compounds known, obtained by the action of this substance upon unsaturated hydrocarbons, and these compounds appear especially interesting if we remember that the nature of india-rubber, as that of an unsaturated hydrocarbon, is one of the few well-established facts regarding the chemical constitution of this product. Guthrie† obtained ethylene chlorosulphide,  $(C_2H_4)_2.S_2Cl_2$ , and amylene chlorosulphide,  $(C_5H_{10})_2.S_2Cl_2$ , by acting upon ethylene and amylene respectively with chloride of sulphur. Both these compounds are heavy oily liquids, which readily give up their chlorine to various reagents without suffering any change in their constitution. The removal of the sulphur, however, seems to be almost impossible without destroying the molecule. Indeed, it appears that the sulphur can only be got at by treating those compounds with strong oxidising agents, the action of which invariably results in a complete breaking up of the molecule. These chlorosulphides are saturated substances, and their constitution is respectively—

We observe now the important fact that these compounds are addition products pure and simple. This fact becomes of the greatest significance if we remember that india-rubber must be chemically described as a poly-isoprene (poly-prene), and that isoprene itself is one of the five isomeric

pentenes which on their part are derived from five isomeric amylenes.

These chlorosulphides, as already stated, are perfectly saturated bodies, but we see at the same time that the characteristic feature of the reaction between the unsaturated hydrocarbon and the chloride of sulphur is not so much the production of a saturated addition product, but essentially the condensation, or rather conjugation, of two molecules of the hydrocarbon by means of the double sulphur atom. As long as this double atom maintains its function, we may remove the chlorine from these addition products or substitute other elements or radicals for it without in the least altering the general character of the compound.

The products of the action of chloride of sulphur upon the triglycerides of the unsaturated fatty acids are evidently compounds of a similar order. It has been impossible so far to isolate from these products well-defined chemical individuals, chiefly in consequence of the almost absolute insolubility of these compounds in all solvents. But it has been known for some time that these products, which are extensively used as india-rubber substitutes, contain both sulphur and chlorine as essential constituents. Quite lately Ulzer and Horn,\* and especially Henriques,† proved conclusively that these india-rubber substitutes contain sulphur and chlorine in the same proportions in which they form chloride of sulphur. These results are of course directly opposed to Thomson's figures, which, however, have been obtained by such a questionable method that they cannot be taken seriously.

Though limited, our present knowledge on the action of chloride of sulphur upon the before-mentioned unsaturated compounds affords some important hints regarding the chemical process of the vulcanisation of india-rubber by chloride of sulphur. It seemed to me important to investigate this vulcanisation process under such conditions that the total quantity of the rubber employed for each experiment would take part in the reaction at the same rate and to the same degree, and to carry out the experiments in such a manner as to preclude secondary reactions due to impurity of the materials employed. All former experiments on this subject did not comply with these conditions, the experiments always being carried out by immersing thin sheets of india-rubber in solutions of chloride of sulphur in carbon bisulphide. However thin the sheets so treated might be, their conversion into a homogeneous compound will be always doubtful, if only because it is uncontrollable; and further, in withdrawing the sheet so treated from its vulcanising solution almost instant volatilisation of the carbon bisulphide takes place, and this is always accompanied by the formation of a film of moisture or dew upon the surface from which the volatilisation takes place. The result is that the excess of sulphur chloride which is contained in the carbon bisulphide adhering to the rubber sheet, is decomposed by this moisture into free sulphur and hydrochloric acid. I proceeded therefore in this manner that I dissolved in 1,000 cc. of pure benzene, which had been twice distilled over sodium wire, 50 grms. of best Pará rubber which had been purified by fractionate precipitation from its solution in chloroform by means of alcohol. This solution was filtered through a fluted filter in a hot-water funnel, and to the beautifully bright solution so obtained a solution of 50 grms. of twice distilled chloride of sulphur in 200 cc. of pure benzene was added, the mixture thoroughly shaken and the flask containing it connected with a mercury barometer by means of a stopper and tube. After about five minutes standing the reaction began to set in, the mixture becoming somewhat gelatinous, but otherwise exhibiting no outward appearance of any change taking place. After 20 minutes the reaction had evidently reached its end; the contents of the flask being converted into a moderately stiff jelly, the firmness of which did not show any further increase. During this time the temperature of the mass had risen about 4° C., and the barometer registered only a barely corresponding higher pressure, which disappeared as soon as the contents of the flask had cooled

\* Loc. cit.

† Ann. Chem. 113, 270.

\* Mittheil. d. techn. Gewerbemus., 1899, 43.

† See present number of this Journal, page 47.

down to their original temperature. Not the faintest trace of the evolution of any gas appeared during the whole of this time, the contents of the flask remaining clear and absolutely undisturbed from beginning to end. This experiment was several times repeated with the same result. Already now it can no longer be doubted that Fawcitt's observation of an evolution of hydrogen in this reaction must be erroneous, as well as the statements of Burghardt, Terry, and Thomson respecting evolution of hydrochloric acid. Evolution of hydrogen in this reaction is in itself almost a chemical impossibility, but hydrochloric acid gas is indeed given off, if not every trace of water has been removed from the india-rubber and the benzene from which the solution is prepared. The evolution of hydrochloric acid in this case is simply caused by the decomposition of the chloride of sulphur by the water, but has no connection whatever with the reaction which takes place between the chloride of sulphur and the india-rubber.

The purification of the product of the above reaction was carried out in the following manner:—The gelatinous contents of the flask were found to be absolutely insoluble in all available solvents, *i.e.*, solvents which will not cause the decomposition of the excess of chloride of sulphur which is present. The whole mass was therefore placed in a bag of fine calico, this was immersed in pure benzol, and the contents of the bag then squeezed through the meshes of the fabric. In this manner the jelly was easily converted into a pulp, consisting of very fine flakes of the product of the above reaction. The excess of chloride of sulphur present was dissolved in the benzene. It is scarcely necessary to remark that the benzene used for this last operation must also be absolutely free from water to prevent decomposition of the chloride of sulphur. The whole is then filtered and the filter residue washed with warm benzene until the filtrate is free from every trace of chloride of sulphur. The filter residue was then quickly pressed between filter paper, transferred to a large Soxhlet apparatus, and during 12 hours extracted with pure carbon bisulphide. The extracted product, still saturated as it was with carbon disulphide, was then quickly transferred into a flask containing absolute alcohol, the flask connected with a condenser and so much alcohol distilled off until the distillate no longer gave the phenyl hydrazine reaction for carbon bisulphide. The contents of the flask were then filtered, the filter residue pressed between filter paper and dried *in vacuo*. A mass of fine yellowish white and very friable flakes was thus obtained. If before drying this substance every trace of benzene or carbon bisulphide has not been removed the substance dries in the form of horny granules of enormous toughness, which resist all attempts to reduce them to a powder.

The substance so obtained is perfectly insoluble in all solvents, although in its behaviour against them it exhibits marked differences. Methyl alcohol, ethyl alcohol, glycerol, acetone, ethyl ether, ethyl acetate, amyl acetate, glacial acetic acid, and acetic anhydride have no effect whatever upon it. The coal-tar hydrocarbons, chloroform, carbon tetrachloride, carbon bisulphide, all the terpenes, eymene, and the etheral oils cause it to become transparent and swell it more or less considerably. But neither in the cold, nor by gently heating the solvents, are the faintest signs of solution observable. On prolonged heating to temperatures above 140° C. more or less complete solution takes place with mesitylene, eumene, eymene, the heavy petroleum hydrocarbons, and all terpenes.\* But there is little doubt that these solutions do not contain the original substance, but merely products of its decomposition at these high temperatures. This conclusion is justified by the fact that on heating the substance in question in the drying oven to a temperature of about 80° C., decomposition sets in with evolution of large quantities of hydrochloric acid. Moreover, the original substance cannot be recovered from the above-mentioned solutions.

The analysis of this substance gave the following figures:—

	I.	II.	Calculated for $C_{10}H_{16}S_2Cl_2$
C.....	43.61	43.51	44.28
H.....	6.21	6.14	5.90
S.....	23.88	23.81	23.62
Cl.....	25.97	26.11	26.19

The most remarkable result of these analyses is the fact that this substance contains S and Cl in the identical proportion in which they occur in chloride of sulphur, just as we found them in the chlorosulphides of ethylene and amylene, and also in the products obtained by the action of chloride of sulphur upon the triglycerides of the unsaturated fatty acids (india-rubber substitutes).

From these results we arrive at the conclusion that india-rubber vulcanised with chloride of sulphur is an addition product of these two compounds, polyprrene-sulphochloride. As already mentioned, the chlorine is very easily removed from this compound and escapes in the form of hydrochloric acid at a temperature of between 80° and 120° C. This removal of the hydrochloric acid may also be effected by boiling the sulphochloride with alcoholic potash. This is a reaction of the same kind as the one Henriques\* observed in treating india-rubber substitutes with alcoholic potash, in which case he obtained unsaturated fatty acids which still contained sulphur, but no chlorine. Of the same order is evidently the elimination of hydrochloric acid from the nitroschlorides of the terpenes:—

The analysis of polyprrene sulphochloride boiled with alcoholic potash for several hours, gave the following figures:—

	I.	II.	Calculated for $C_{10}H_{16}S_2$
C.....	59.88	59.93	60.60
H.....	7.21	7.47	7.07
S.....	32.11	32.04	32.22

The product thus obtained is, therefore, evidently polyprrene sulphide, all the chlorine of the sulphochloride being eliminated. According to Thomson\* and Terry,\* who assign the vulcanising action of chloride of sulphur to its chlorine, we should expect now this polyprrene sulphide to have lost all the characteristic properties of vulcanised india-rubber and to differ very widely in its properties from polyprrene sulphochloride. But as a matter of fact this elimination of the chlorine alters the properties of our vulcanisation product so little, that without the analytical data we could not form any opinion as to whether alcoholic potash has any action at all upon the sulphochloride. In all its physical and chemical properties polyprrene sulphide cannot be distinguished from perfectly vulcanised india-rubber, especially its absolute insolubility and chemical indifference have remained the same as we found them in the sulphochloride. While it is thus shown that the removal

\* See also Henriques, this Journal, 1893, 468.

\* Loc. cit.

of the chlorine from polyprene sulphochloride can be effected with the greatest ease and without causing any structural alteration of this compound, any attempt to remove the sulphur is either unsuccessful, or results in a total destruction of the substance. These observations leave no room for any doubt as to whether the vulcanising action of chloride of sulphur is due to the sulphur or the chlorine of this compound, especially if we find that the state of vulcanisation remains the same with or without the chlorine. Therefore, although the chlorine and the sulphur of chloride of sulphur act simultaneously upon the india-rubber, it is the sulphur to which the vulcanising must be attributed. It is somewhat strange that Thomson, Terry, and Hurgbardt pronounced the vulcanising action of chlorine without supporting it by further experimental evidence, at least by a closer investigation of the halogen derivatives of india-rubber. They would then have found that although these derivatives in outward appearance very closely resemble vulcanised india-rubber, they are clearly distinguished from it by their great and complete solubility in benzene or chloroform. But these halogen derivatives do not even possess the chemical stability of vulcanised india-rubber and readily lose all their halogen under a variety of conditions. These halogen derivatives will be specially treated in the second part of this paper.

The above quoted analyses lead to the formulae  $C_{10}H_{16}S_2Cl_2$  and  $C_{10}H_{14}S_2$  for polyprene sulphochloride and polyprene sulphide respectively. Whether these formulae indeed represent the respective molecular weights of these compounds is a most important question, but all the means usually employed for the determination of this factor are quite unavailable in this case owing to the impossibility to vaporise these compounds without decomposition or to dissolve in some indifferent solvent. On the other hand, however, it can be shown from purely chemical reasons that those formulae do not even approximately represent the molecular weights of polyprene sulpho-chloride and polyprene sulphide, as if they did the molecular weight of india-rubber itself would appear to be  $C_{10}H_{16}$ , which certainly is not the case, as we shall see presently.

I have been referring above to the addition products obtained from ethylene, or amylene, and chloride of sulphur, and I showed that these products are formed by the coupling together of two molecules of the hydrocarbon by the sulphur of the chloride of sulphur, thus—

Consequently in acting upon terpenes with chloride of sulphur compounds must be obtained, the molecular weight of which cannot be lower than  $C_{20}H_{32}$ . Lately Henriques,\* in his excellent studies on the analysis of india-rubber articles, showed that of two sheets of pure Pará rubber which were cured by immersion in solutions of chloride of sulphur in carbon bisulphide, the sheet containing 5 per cent. of sulphur was over vulcanised, consequently rather stiff and hard, while the second sheet, which contained 0.5 per cent. of sulphur, was underdone, and therefore still somewhat tacky. But our above described polyprene sulpho-chloride contains 23.8 per cent. of sulphur, and practically consists of equal parts of india-rubber and chloride of sulphur. In practical working, therefore, such a vulcanisation product is never produced, as it would be almost equal to a complete destruction of the india-rubber for practical purposes. But at the same time, we have to consider the fact that india-rubber will combine with its equal weight of chloride of sulphur, forming a vulcanisation product with over 23 per cent. of sulphur, so that the question arises as to whether india-rubber vulcanised for practical purposes and containing a possible maximum of 5 per cent. of sulphur, may represent a homogeneous compound, or must under all circumstances be regarded simply as the solution of a corresponding quantity

(about 20 per cent.) of polyprene sulphochloride  $C_{10}H_{16}S_2Cl_2$  in unaltered india-rubber.

To decide this point, 5 grms. of purest Pará rubber were dissolved in 1,000 cc. of pure benzene, and 5 grms. of chloride of sulphur were added to this solution. In consequence of the great dilution the reaction proceeded very slowly, but after three hours standing all the chloride of sulphur had disappeared. The solution was left standing overnight, and on the following morning 100 cc. of it, representing 2 grms. of the india-rubber used, were treated with absolute alcohol and the polyprene sulphochloride, which separated out purified in the manner before described. An analysis of this compound again showed 23.78 per cent. of sulphur, so that there is no doubt about the conversion of the india-rubber in the sulphochloride  $C_{10}H_{16}S_2Cl_2$ , even in such dilute solution, provided there be the required amount of chloride of sulphur. To the remaining 600 cc. of the above-mentioned solution, a solution 22.5 grms. of pure Pará rubber in 200 cc. of benzene was now added, and the mixture strongly agitated. The gelatinous character of the mixture rapidly changed into that of an ordinary india-rubber solution, and on pouring this solution into absolute alcohol a voluminous precipitate very much like polyprene sulphochloride was obtained. This precipitate was separated from the supernatant liquid by filtration, the filter residue repeatedly washed with warm alcohol, and then dried *in vacuo*. In this manner a rather elastic substance was obtained, which, on analysis, was found to contain 4.96 per cent. of sulphur, or about as much as Henrique's high vulcanised india-rubber sheet. The question is now whether this new product really possesses the properties of commercially vulcanised india-rubber. To determine this point the substance was placed in benzene. After 18 hours standing, complete solution had taken place; the solution appeared somewhat turbid. It was strongly diluted, and filtered through a hot-water funnel. The filtrate obtained was beautifully clear. On the filter remained a residue, which was repeatedly washed with warm benzene and then dried. It formed a whitish, easily friable mass, weighing 5.8 grms., and on analysis it was found to contain 23.41 per cent. of sulphur. There is no doubt that this substance represents the total quantity of polyprene sulphochloride we mixed with india-rubber, and this is further confirmed by the fact that the above-mentioned filtrate contains not the faintest trace of either chlorine or sulphur. This result is a conclusive proof that a mixture of polyprene sulphochloride and india-rubber only possesses the properties to be anticipated for such a mixture, but not those of vulcanised india-rubber. This being so, we must at once come to the conclusion that india-rubber vulcanised with chloride of sulphur and containing a maximum of 5 per cent. of combined sulphur, must be a homogeneous compound in the sense that every molecule of india-rubber present is combined with sulphur and chlorine, and that there is no uncombined india-rubber. But this, of course, is only possible if the molecule of india-rubber is very much larger than  $C_{10}H_{16}$ .

Before proceeding any further it was important to prove that india-rubber homogeneously vulcanised with such a quantity of chloride of sulphur as to produce a product containing again 5 per cent. of combined sulphur, behaved distinctly different from the above mixture. For this purpose 25.5 grms. of purest Pará rubber were dissolved in 1000 cc. of pure benzene. To this solution 3 grms. of chloride of sulphur were added, the mixture vigorously stirred and then left to stand. Very soon the mass began to thicken, the reaction reaching its maximum after about 15 minutes. After several hours standing the jelly was thoroughly broken up by stirring, and the resulting pulp poured into absolute alcohol, the precipitate was filtered off, adhering and occluded benzene driven off in the well

\* Of course in vulcanising, say, waterproof cloth, with chloride of sulphur, it is well known that only the surface of the india-rubber coating becomes vulcanised, the lower strata receiving very little, if any, of the vulcanising agent. This has, however, nothing to do with the above question, the point being as to whether that part of the india-rubber which did get vulcanised possesses the composition,  $C_{10}H_{16}S_2Cl_2$ , or is a vulcanisation product with less sulphur. And if so, whether such a vulcanisation product is a homogeneous compound or a mixture of the above-mentioned description.

\* See page 70, this Journal, present number.

known manner, and the substance finally dried *in vacuo*. The dry substance contained 5.11 per cent. of sulphur, and is therefore in this respect identical with the mixture of polyprène sulpho-chloride and india-rubber. The elasticity of the new substance is, however, greatly superior to that of the mixture, from which it further differs essentially by its absolute insolubility in all solvents. Even an immersion of weeks at a time utterly fails even to soften it, although considerable swelling of the immersed substance takes place. This, however, is also the case with our sulpho-chloride of the formula  $C_{100}H_{180}S_2Cl_2$ . It is evident that this substance, containing only 5 per cent. of sulphur, does not contain any unaltered india-rubber, and must be considered as sulpho-chloride, distinctly different from  $C_{10}H_{16}S_2Cl_2$ , which contains nearly 24 per cent. of sulphur. The only possible explanation of this observation is that the molecule of india-rubber possesses a considerable number of ethylene bonds which react successively with chloride of sulphur in the already explained manner:—

every fresh molecule of chloride of sulphur producing such a sulphur bond between two molecules of india-rubber. With the number of such bonds in one molecule of the vulcanisation product the hardness and indifference of this product must increase. This unavoidable inference appears to me of considerable interest for the explanation of the process of manufacturing ebonite, which is altogether in the dark as yet.

A very simple calculation shows now, that a vulcanisation product containing 5 per cent. of sulphur must possess a molecular weight of about 1,300, and this almost exactly corresponds to a compound  $C_{100}H_{180}S_2Cl_2$ . Taking into account that one molecule of chloride of sulphur will copulate two molecules of india-rubber, in the manner repeatedly alluded to, the above formula would have to be dissolved into—

Accordingly the molecular weight of india-rubber has to be taken as  $C_{50}H_{90}$  or  $(C_{10}H_{18})_5$ , and accordingly our first described polyprène sulpho-chloride must possess the formula  $[C_{50}H_{90}]_2 \cdot 10S_2Cl_2$ . If we calculate according to this formula the lowest vulcanisation product (sulpho-chloride) india-rubber is capable to form, we find that it would be one containing 4.20 per cent. of sulphur. Such a product was prepared by dissolving 90.97 grms. of pure Para rubber in 4,500 cc. of absolutely dry benzene and adding to this solution 9.03 grms. of chloride of sulphur dissolved in 100 cc. of dry benzene. The reaction proceeded very rapidly, but the mass was left standing for several hours after the reaction had come to a standstill. The rubber solution was then found to be converted into an exceedingly viscous jelly, which was perfectly free from stickiness. This jelly was squeezed through very fine silk gauze into alcohol, where it separated out in the form of very small and elastic pieces of a whitish colour. The substance so obtained was freed from every trace of benzene in the manner before mentioned and then dried.

On analysis this product was found to contain 4.26 per cent. of sulphur, and 4.71 per cent. of chlorine. It possesses all the properties of well vulcanised india-rubber, especially very great elasticity and great indifference against changes of temperature. In the well-known solvents for india-rubber this vulcanisation product swells very considerably, without, however, even on very prolonged treatment, ever exhibiting the faintest sign of solubility. This leaves no doubt that it contains no free india-rubber, a fact which can only be explained by attributing

to it the formula  $C_{100}H_{180}S_2Cl_2$ , or rather  $(C_{50}H_{90})_2 \cdot S_2Cl_2$ . As before mentioned, our old formula for polyprène sulpho-chloride,  $C_{10}H_{16}S_2Cl_2$ , must accordingly, be altered to  $(C_{50}H_{90})_2 \cdot 10S_2Cl_2$ . If we now examine the formulae of these two compounds we see at once that while each contains two molecules of india-rubber of the formula  $C_{50}H_{90}$ , there is a wide difference between the amount of chloride of sulphur they contain, and it is evident that between these two polyprène sulpho-chlorides eight others must exist containing from two to nine molecules of  $S_2Cl_2$ , and from the vast difference in the physical properties of these two end products of the series we may safely conclude that every one of these ten possible vulcanisation products will have distinct properties which distinguish it from any of the other nine members of the series. It will be a matter of the greatest practical importance to define clearly the specific properties of each of these ten vulcanisation products. There is no doubt that the degree of vulcanisation of an india-rubber article must vary, and ought to be regulated according to the very varying uses these articles are put to, and certainly the manufacturers are fairly well aware of this truth, although I do not think that they have given it half the attention yet which it deserves. This is probably and in a large measure due to the fact that the *rationale* of the vulcanisation process so far has not been properly understood, although it certainly has been misunderstood. Consequently our present means and ways to carry vulcanisation always to the same stage, or to some definite stage, are in a very crude state as yet. Indeed I am justified in saying that vulcanisation so far is still on materially the same point to which the labours of Goodyear, Hancock, and Parkes advanced it, and there is ample room for improvement.

It would be beyond the scope of the present paper to enter into a closer investigation of the properties and technical applicability of the ten vulcanisation products above named. This may in itself be the subject of a probably rather extensive paper, as it will be necessary to devise altogether new methods for the practical vulcanisation of india-rubber articles. In the present paper I have not directly been aiming at practical results in regard to vulcanisation, but rather restricted myself to the scientific side of the question, which is the only ground upon which technical points of this kind can be satisfactorily discussed and advanced. I may, however, perhaps point out that at the present moment the vulcanisation of india-rubber articles with chloride of sulphur is of a rather limited applicability, the vulcanising through of anything like a substantial thickness of india-rubber, or even the homogeneous vulcanisation of thin rubber films, being impossible with this vulcaniser, on account of its rapid and energetic action upon india-rubber. Nevertheless, I feel justified in already now expressing the opinion, proof of which I shall furnish in the next paper, that the vulcanisation process of the future for india-rubber articles of every description, will be some process based upon the chemical theory of the chloride of sulphur vulcanisation as above propounded. No doubt there are considerable difficulties in the way of this improvement, but they are not insurmountable, and from certain observations in advance of the present paper, I infer that by such a new process the ordinary chloride of sulphur cure (cold cure), as well as the sulphur cure (dry heat and steam cure), will be altogether superseded, and I really doubt very much whether the latter will be able to hold its own even in the manufacture of ebonite. Indeed I have no hesitation in saying that the sulphur cure as in use at present is an exceedingly crude, unreliable, antiquated and unscientific process, which is being kept alive only by our ignorance of the chemistry of india-rubber.

I can hardly expect that the molecular weight for india-rubber, which I deducted in a somewhat unusual manner from the polyprène sulpho-chlorides as  $C_{50}H_{90}$  will be accepted without comment. While maintaining that on the one hand the methods and arguments I used for the purpose cannot be objected to, I am on the other hand bound to admit that there is still a possibility of the size of the india-rubber molecule being even greater than I stated it, namely, twice  $C_{50}H_{90}$ , or even more. To settle this point definitely only one of the physical methods for the estimation of the

molecular weight can be relied upon. Hibbert and Gladstone\* have already made attempts in this direction by determining the depression of the freezing points of solutions of india-rubber. The results these authors obtained were so unsatisfactory that they themselves regard them with a great deal of doubt, and I may at once say that my own results by that method are no better. There was still the possibility that the boiling point method might prove successful, but the figures obtained by its means soon dispelled this illusion. This, no doubt, in both cases is due to the colloidal state of solutions of india-rubber. Ostwald,† Luedeke,‡ and others found that solutions of colloidal substances show almost immeasurably small depressions of the boiling and freezing point. Until we are able to obtain easily soluble and non-colloidal derivatives of polyprène, the probability to confirm or correct by physical means the above propounded molecular formula of polyprène is very remote. For this reason the formula  $C_{50}H_{80}$  strictly speaking can be considered to represent a minimum only, as the real molecular weight of polyprène might be a multiple even of that formula. I expect to be shortly in position to settle this point definitely.

The results of this investigation may be shortly summed up as follows:—

1. The action of sulphur monochloride upon polyprène is identical with the action of sulphur monochloride upon the unsaturated hydrocarbons of the ethylene series; that is to say, two molecules of polyprène are linked together by one or more double atoms of sulphur. Every molecule of sulphur monochloride entering into reaction dissolves one ethylene bond in each of the two molecules of polyprène.

2. At least ten different polyprène sulpho-chlorides exist, containing from one to ten double atoms of sulphur.

3. The vulcanisation of india-rubber consists in the formation of one or more of these polyprène sulpho-chlorides. The state of vulcanisation is due to the presence of these sulphur bonds, by which a condensation or conjugation of two molecules of polyprène into one molecule is effected. The presence of the chlorine in the vulcanisation product is without influence upon the state of vulcanisation. It is merely the means, in the chloride of sulphur, which enables us to act upon polyprène with a double atom of sulphur *in statu nascendi*.

4. The practical process of vulcanising with chloride of sulphur is most imperfect, as it does not admit of a homogeneous vulcanisation of the india-rubber. A process for the homogeneous vulcanisation of india-rubber by means of a method based upon the reaction between polyprène and sulphur monochloride, would be of very great practical value, and by far preferable to any of the vulcanisation processes now in operation.

#### DISCUSSION.

The CHAIRMAN gathered from the statements of Dr. Weber that no scientific progress had been made during the past fifty years with regard to the important industry of vulcanising india-rubber. This was because neither solvents nor other agents seemed to have any great chemical action upon that substance, and there had been great difficulties in the way of anyone starting a theoretical research on the possible combinations of this substance, and he was glad that Dr. Weber had resolved the moot points as to what chemical action did take place when india-rubber was subjected to the action of chloride of sulphur. The author had shown that a combination was formed of a definite compound containing both sulphur and chlorine, and that chlorine did not play an active part in the end on the properties of the vulcanised substance. This in itself was a wonderful result, and differed from those admitted by former searchers in this field.

Mr. TERRY admitted that he had perhaps been too ready to accept the explanation as to the theory of vulcanisation advanced by Burghardt, but he had never looked on the matter as at all settled. In regard to the passage objected to by Dr. Weber, the opinions then expressed were never intended to be more than a provisional hypothesis to form

the basis of future inquiry. Such opinions, founded on analogy alone, must of course give way before the practical results of Dr. Weber, though in the light of the known action of chlorine on rubber it was not so very far fetched to attribute a somewhat similar action to chloride of sulphur. It was not easy to discuss such a paper without seeing it in print, and he should defer any further remarks until the occasion of the reading of the second part.

Dr. WEBER, in reply, quite agreed with Mr. Terry's remarks. He did not propose to do away with sulphur vulcanising and do it all with chloride of sulphur. What he said was that he could see the possibility of devising some method for the vulcanisation of india-rubber, based upon the same reaction as that taking place between chloride of sulphur and india-rubber. He quite saw a way to getting at a substance that would be capable of the same reaction without the drawbacks of chloride of sulphur. Before the chloride of sulphur had time to penetrate the articles to be vulcanised, its chemical action had already been exhausted by combination with the superficial strata. Mr. Terry would be able to bear him out, that on the vulcanising of cloth with chloride of sulphur, they would always find that the india-rubber on the back was absolutely unvulcanised. This precluded altogether the idea of homogeneous vulcanisation. The importance of chloride of sulphur lay in the fact that it allowed them to vulcanise at ordinary temperatures. With sulphur they had to use high temperatures. He had actually found that direct harm was done to the india-rubber through the excessive heat which was necessarily employed. It was quite true the temperature could be decreased very considerably by using an excess of sulphur, but this was almost worse than working at high temperatures.

The chlorine of the chloride of sulphur, which, together with the sulphur, entered into combination with the india-rubber, was utterly immaterial for the state of vulcanisation. All the characteristics of india-rubber remained unimpaired after the removal of the chlorine from the vulcanisation product, provided only they had the sulphur bond intact. Now, if india-rubber were treated with chlorine or chlorinating agents, substances were obtained which physically very closely resembled vulcanised rubber. They were, however, easily distinguished from the former by their great and complete solubility in chloroform. At temperatures very little above the boiling point of water the chlorine derivatives of india rubber lost their chlorine completely, a hydrocarbon differing materially from india-rubber remaining behind. It was therefore evident that the chlorine derivatives of india rubber, although in some respects similar to vulcanised india-rubber, were utterly deficient just in the most important properties of the latter.

### CHAIRMAN'S ADDRESS.

BY PROFESSOR ARTHUR SMITHELLS, B.Sc.

It is the duty of my position this evening to address you on some subject of general interest to those who are engaged in chemical industry. I trust you will pardon me if I choose a subject which though very stale, is one that concerns me closely, and one on which I am really anxious to have my say. I mean chemical education so far as it concerns chemical industries. You may ask me, can there possibly be anything new to say on this subject—is it not already worn out? Perhaps there is not anything new to say, but I do feel this, that the teacher has not had his share of the talk. If there is one subject more than another in which everyone claims a right to lay down the law, it is in education, and especially technical education, and we are becoming day by day more bewildered and entangled in a network of schemes and doctrines which defy all orderly adjustment. The race seems to have been educated to the point of seeing that the human body is a complicated mechanism, the care and discipline of which had best be relegated to a professional brotherhood who have made a special study of its working. But we do not seem to have realised that if the body is complicated the mind is more so, and that the means of making it an effective instrument and of giving it the sustenance it demands in the best possible way, is quite as much a matter for skilled opinion.

The importance of chemistry in relation to industry has been recognised in a vague sort of way ever since the chemical industries became at all considerable. It has been felt that all who have been engaged in such industries might become more intelligent in them by learning something of the general principles and chief facts of chemical science. It has been proved again and again that a deeper knowledge of this science has enabled some of those who have had the capacity, and means, and opportunity of acquiring such knowledge, to effect important changes and innovations in chemical industries. As time advanced, as these industries became more numerous and of greater national importance,

it seemed desirable to set in motion some machinery for providing this desirable dissemination of chemical knowledge. This was particularly illustrated by the great Exhibition of 1851, and in 1853 the Science Division of the Science and Art Department was established in order "to extend a system of encouragement to local institutions for practical science." Accordingly, experimental schools were started in various parts of the country. These were so far a failure, that in 1859 only four such schools survived in Great Britain, and the sum total of the science students was 400. It is difficult at this distance to ascertain the cause of this poor result. It may have been that the teaching was not good, or that it was not well paid, but I am inclined to think that it may have been due mainly to sheer apathy both of the potential teachers and potential students. It was then as it is to-day, to offer education without easily visible gains is to dangle a hare before the fish.

In 1859, someone, whose name had best remain in obscurity, invented the device of payment on results. From that time chemistry classes multiplied on the face of the earth and they have gone on multiplying ever since. In the seventies there were not many districts in which chemical industries existed that could not offer to the employes the opportunity of becoming more or less acquainted with chemistry. Schools likewise—grammar schools, rose from their torpor and shook themselves, throwing out "modern sides" which frequently embraced chemistry as one of the subjects of instruction.

So much then for the general dissemination of chemical knowledge which was to lighten the lump, to give the artisan an intelligent appreciation of the principles of the science which underlay his daily work. Now for the other part of the problem—how to train the experts. The means were in existence from the first. The College of Chemistry with the giant Hofmann (would that he had stayed with us!) came into existence in 1845. Owens College, and with it almost immediately Roscoe, were established in Manchester in 1851. After a considerable interval other great towns produced their university colleges, and in the seventies there was a good supply of institutions where chemists could be trained into investigators, and where many chemists were so trained.

Here then was the apparent solution of the problem so far as chemistry was concerned. What more was wanted? I ask the industrial chemists before me—what more do you want than this, an opportunity for all to learn the general principles of the science and an opportunity for the few to become chemical investigators? You will answer this question by asking me another—"was this a reality that you have pictured?" I answer unhesitatingly that it was not—it was not a working system, and if you ask me for proof I will simply say this, that for the last ten years the land has been ringing with the cry for what in chemistry was supposed to have been obtained, namely, chemical education adapted to the needs of industry. The cry is merged in a very babel of sound about the very bogey of a name—"technical instruction"—but it is there clearly distinguishable. Let us neglect everything but chemistry—for the rest is not our business. Surely it is worth pondering, that although ten years ago we had apparently realised the primary objects of those who wished to direct chemical instruction into industrial channels, we are talked at to-day as if nothing had been done.

I will ask you to bear with me whilst I state to you my own explanation of the anomaly. Superficially and summarily it is this—that somehow it has become implanted in the public mind that in chemistry there is an intermediate realm of knowledge which is free from the abstractions and futilities of pure science, yet in its nature scientific; which has for its apparatus something between the beaker and the boiler; for its teacher something between the professor and the unpolluted practical man; for its goal pure gold.

This, I believe, is a fair rendering of the vague feeling that prevails, and its prevalence would seem to indicate that our previous efforts to apply chemistry to industry have been unavailing. Let us look, therefore, at the means that have been tried and found wanting. We have to deal with the general instruction of the many and the extended

training of the few. The means have been for the first the Science and Art Department, for the second the universities and university colleges.

I do not propose to enter into a detailed criticism of the chemical teaching promoted by the Science and Art Department. It has often formed the theme of denunciation, less frequently of faint praise; never, so far as I know, of enthusiastic commendation. I confess that I am impatient of the tolerance with which it is regarded by so many. No doubt much good teaching has been done under the auspices of South Kensington, but a good teacher will do good work under any system. The question we have to ask is whether the system naturally conduces to good teaching, and to that question I fear we must return a negative answer. Until quite recently the chemistry teacher under the Science and Art Department was bound to teach chemistry the wrong way about. Instead of beginning with everyday things and phenomena, he had to start formally with the technicalities of the subject, as in a college course. Air did not lead to oxygen, but oxygen to air; water not to hydrogen, but hydrogen to water; a candle-flame not to chemical combination, but chemical combination with formulæ, equations, and all the paraphernalia of the chemist, eventually to the candle-flame. Latterly, an immense advance has been made by the framing of an alternative first stage of instruction, which is really a chemistry of common things, and an admirable introduction to the subject. But this relief is largely illusory, for if a teacher puts his class through the course and obtains grants on the results of the examination, he has to take the pupils right on to the advanced stage before he gets more grants. If he follows the natural sequence of taking the ordinary elementary syllabus after the "alternative" course, he has to teach for nothing. The consequence is that a great many teachers who (as they have assured me again and again) would greatly prefer to begin with the rational introduction furnished by the alternative first stage, omit it altogether, in order simply that they may live. The practical work which accompanies the first stages of South Kensington chemistry consists essentially in cultivating the art of detecting simple salts—a pursuit which I believe is generally regarded by the youth of this country in the light of an agreeable indoor recreation of the "puzzle" order. It is usually done with a zest easily mistaken for intellectual zeal and very impressive to the casual observer. What good intellectual or practical purpose this "test-tubing" serves, I have never been able to discover, unless that it provides the basis for a practical examination suitable to the exigencies of the Department. Do not think I undervalue analysis as a means of training. In the training of a chemist analysis is the backbone of his education. But for familiarising the schoolboy with the leading facts and principles of every day chemistry, it is, in my judgment, worse than useless, and its imposition not justified by the fact that a more profitable kind of work would be more difficult to examine.

I shall not speak about the later stages of the chemistry of the Science and Art Department. The beginning is everything. If that is not good, the later stages can only be so by accident. In my opinion, there is a tendency to teach far too much chemistry in schools—so far as the syllabus is concerned—and I prefer infinitely to receive as students those who have been intelligently taken through the alternative elementary stage rather than those who have attained to the doubtful glory of a "second-class advanced."

Perhaps the most conspicuous blot on the South Kensington system of teaching has been the absence of anything like real inspection. There have been four permanent inspectors to control the whole of the classes in all the science subjects patronised by the Department. In order to eke out an even nominal inspection it has been necessary to enlist as auxiliaries a large force of military officers stationed in various parts of the country, and the inspection has been very largely in their hands. This inspection has been, as a rule, merely statistical, the inspectors knowing nothing of the subjects taught, and still less of the proper method of teaching them. The inspection has, in fact, been a farce, and from what I have seen I think no one

has felt this more than the officers themselves.\* The consequence has been that the only control of the teaching has lain in the May examinations, when the teacher has been paid "on results." I need not spend time in preaching against the system of payment by results. It is a doomed system, but I fear it will die a lingering death at South Kensington. There is just one more point in reference to the Science and Art Department chemistry that I wish to mention. Chemistry figures as a subject of instruction under the Whitehall "Code,"—entirely apart from South Kensington. Recent changes in the Code have made it possible to teach chemistry in a really satisfactory manner in our elementary schools. But it is also the case that in the higher standards the teacher may, if he likes, desert the Code and go under the Science and Art Department. By doing so he would make an educational sacrifice, but obtain a very greatly increased grant. Can one wonder that, under these circumstances, the teacher, as the phrase goes, "runs the pupils for South Kensington"?

I think that I have now said enough to make it clear why the teaching of elementary chemistry under the influence of the Science and Art Department has not realised the end in view. I do not think it is the least surprising that by a system taught with so many deficiencies and anomalies we have failed to bring about a general dissemination of elementary chemical knowledge—useful in the sense of education or of instruction which should be the basis of specialised study. Nor do I think it surprising that we should have failed to impress the public with the educational or purely utilitarian value of science teaching.

Having described South Kensington as it was and is, I now pass to the institutions for training experts. It would be unbecoming on my part to attempt to state how far I and my brother professors of chemistry are cut out for discharging our duties to the community. I trust we have a proper measure of sublime discontent with ourselves. We have most of us got good laboratories, competent help, and enough to keep up a tidy personal appearance. If we are not able to teach chemistry up to the high level that is desirable, it is the fault of the public who appoint us. I will at any rate go so far as to say this, that, given enough ardent and intelligent students, there are not wanting in this country places which will turn out in a reasonable time a supply of chemists trained to the pitch of investigators adequate to the wants of the industrial world. I will ask you at any rate to assume the truth of that proposition. And now comes the important commentary. There are not enough ardent and intelligent students to make into good chemists, and, if there were, the industrial world would not want them.

I will carefully examine this statement. In the first place, it might be said it is a matter of supply and demand. No doubt this is true to a considerable extent, but there is something else. If there were in existence what Professor Huxley calls "a capacity-eating machinery" which would pick out the intelligent pupils from the schools and bring them to the colleges we should turn out more and better chemists whether they were wanted or not. Such as were appropriated would at any rate be good specimens of their kind, and by their practical achievements in the field of industry do more to create right views as to the relation of science to industry than any amount of argument. But, as I have said, they are not wanted. What, then, is wanted?

For a reply to this question I might refer you to innumerable utterances by public men, but I will keep to our own Society, and reproduce a short passage from an address printed in this Journal. It has special reference to dyeing. After a criticism of existing schemes and methods, the following indications are given of the kind of instruction that is deemed better by "practical" men:—

"If, therefore, we want to train in our schools day students destined to become foremen or managers or masters of such works, we must teach them the application of science to these industries, with the appliances and apparatus

\* Since this address was delivered, I have learned with intense satisfaction that a new and highly-qualified inspectorate is to be created for the Science and Art Department.

which they will actually meet with in practice. We must have school workshops equipped with the very latest and most modern machinery of this or any other country, which must be kept on a level with the progress of discovery and invention. We must have a model bleach, dye, print, and finishing works, of course on a small scale, but yet large enough to allow the yarns in our spinning department to be made up, bleached, prepared, dyed, &c., and the cloth woven in our weaving school to be bleached, printed, and finished, and the work turned must not be schoolboy's work, but equal to the best to be found in the trade. Only thus shall we be able to put our student in a position at once to confront and solve all the difficulties and problems which he may encounter in practice, and only thus will his scientific knowledge be of real advantage to himself and the trade."

Let us now examine these proposals. We have, first of all, to make a chemist who shall have a good general knowledge of the science, and a specially good knowledge of the chapters relating to his future pursuits. He must be able to keep abreast of the progress of the science and ready to turn new discoveries to practical account. For a student of intelligence and possessing a good preliminary education, I do not think it extravagant to fix four years as the time necessary for this chemical training. At the end of it he would be a chemist pure and simple—there would have been no time for anything else except the indissociable sciences like mathematics and physics. He is now to be made an engineer. How long this would take is difficult to say. A smattering of engineering may be picked up in a short time, but to make a man a resourceful mechanical engineer is a serious undertaking, and an allowance of one or two years for the purpose does not seem extravagant. Being now a chemist and engineer, our student is to move among the model plant of a model dyeworks. Manufacturers are supposed to have furnished the teacher with their treasured devices and receipts. The institution is to keep the machinery going, and to supply cloth to be dyed and mis-dyed. Shafts are to break, vats to leak, water to foul, and everything to be right and wrong by turns, so as to be as like the reality as possible. Perhaps, by a judicious concentration of misfortunes, six months might suffice to give the student some idea of the ups and downs of a dyehouse.

This is a long and exacting programme, but I do not think it comprises all that is aimed at. A dyeworks chemist has other things to prepare for. If the school is to equip him for the difficulties of his post, there should be in it some model British workmen tied hand and foot by the rules of their union; a model foreman dyer, who, armed with his grandfather's receipts, regards your chemist as a mischievous interloper; and, last of all, there should be a model British manufacturer, ignorant of science, distraught by foreign competition, distrustful of all that is new-fangled, dimly conscious that there is something in science that can help him, but fatally impatient of experiment or investigation.

I trust that the above will not be considered a travesty of the proposals that I have quoted. It is intended to be a serious filling in of the sketch there given. It may be said that the proposals were for the training of managers and foremen, not of experts. But the earlier part of the address which I have quoted is an explicit attack on the expert as at present trained, and the latter part an indication apparently of how he should be trained. In any case I believe the scheme to be impracticable and impolitic, and I do not believe that it is in this way that we shall make science available for the purposes of industry.

What then is to be done? I would reply let us do better what we are already doing badly. Let us by all means train the whole industrial community to an appreciation of science and its relation to the phenomena of nature and the practical arts of mankind. But our aim should be to cultivate their intelligence rather than to specialise their knowledge; and we have to look mainly at imparting a sound and extended general education. For the future masters we may do more. We cannot as a rule make them experts, but we may give them a sound general knowledge of chemistry. We can teach them to look abroad and see

the meaning of the scientific laboratory of a German colour-works. They can be made to see and understand how educated German manufacturers solve the problems of industrial chemistry.

Lastly there is the training of the expert. An expert in chemical industry must principally be a chemist pure and simple. There is only one science of chemistry, and only one set of chemical principles; only one straight course which a man may travel if he is to become a chemist, and that is the unbiased and unabated study of chemistry as a science. If it is true that we speak of the chemistry of this, that, and the other industry, it is just as true that it is chemistry—the one and only chemistry—applied to this, that, or the other set of phenomena. It is, in short, the chemistry of the university. In Germany you find it also (little as this seems to be realised here) in the higher polytechnics. It means in time a bare minimum of four years continuous hard study on the basis of a sound and liberal general education.

If I am asked whether such a chemist is really a productive man, I would reply that it is precisely these men that by their labours in other countries have given such an impulse to foreign industries and such alarm to British manufacturers. It is true that we have in this country and in this Society some splendid examples of the class; they multiply, however, but slowly. It may be that the supply is not great, but the demand is less than the supply. The British manufacturer as a rule wants something more than a mere chemist, or if he does take a chemist from the university, he forms unreasonable expectations, and is soon disappointed. I ask what is it reasonable to expect of a man going to a works as chemist? Is it reasonable to expect him to know the working conditions of a large industrial concern? Is he to have all the resources of chemist, mechanic, mason, and manager? Is he to translate instantly the experiments of beakers and crucibles into boilers and furnaces? Is he to be forbidden the one sure method of progress—the method of learning from mistakes? To these questions a great part of the public opinion of to-day virtually says yes, for it is surely this that is at the bottom of all these schemes for producing chemical engineers.

Fortunately there are some business men who can be business-like, even on the question of availing themselves of scientific help. They will invest their money in a chemist's brains as they will in a new departure in their manufacturing apparatus. They do not simply turn on the steam and excrete if the machine will not work instantly to the advertised standard of efficiency. They are content at first with a small or imperfect output and a dead working loss. But soon, by a reasonable regard to functions and adaptabilities, by giving the thing fair play, it rises to its reputation and more than repays the costliness of its early days. It is precisely thus that a reasonable manufacturer treats his chemist and secures the return on money invested in the machinery of a trained chemical intelligence.

Is there then to be no specialisation in the training of technical chemists? I do not say so. What I maintain is that an unspecialised chemist is in himself a profitable servant, who, if reasonably treated in the works, will soon become a specialist.

I believe in specialisation on the basis of sound chemical education, where it can be reasonably taught. I recognise the existence of a "borderland" in chemistry. I find in the first-rate works chemist a perfect treasury of technical knowledge, much of which might be imparted to others within college walls. Let us have such teaching by all means, but on two conditions—first that it is not at the expense of those foundations of purely scientific chemistry on which alone it can properly rest; secondly, that it is first hand. Borderland knowledge, if it is to be valuable, must come direct from the man of practical experience in the industry concerned. It is one man's work to impart it, for he must be alive to every forward move of the industry and every advance in chemistry. If not, either his chemistry or his technology will be immediately out of date. If specialists can be procured; if you can make it worth their while to teach; if you can give them properly trained students, you will have something in the nature of techno-

logical teaching, which would be an invaluable addition to a purely chemical training.

But such teachers will be neither abundant nor inexpensive, and I do not think they are indispensable. Under the most favourable circumstances there will remain much that the chemist can only learn within the precincts of the works. I believe there is no royal road to chemical engineering, and it is greatly to be feared that those who attempt to find one will emerge neither chemists nor engineers, but with that smattering of both sciences which is such a deceptive and dangerous thing.

In conclusion, let me say that whilst I maintain above all else the necessity of the scientific chemist for the maintenance of chemical industries, I am not insensible to the possibility of doing something for the manager and foreman. They may have their half-loaf of chemical instruction, and it may possibly be best given at technical schools. I do not feel specially interested in the subject, for it seems of such secondary importance, and I am not aware that in their own proper sphere our managers, foremen, or workmen are inferior in aptitude to their foreign rivals. I have asked again and again what is the foreign industry that beats us in consequence of the superior chemical knowledge of the workman. I can get no answer. But no one who has looked into the matter with any desire to learn can ignore the fact that our great and pressing need is the affiliation to our chemical industries of adequately trained chemists. When I say adequately trained I do not mean technically trained. I mean rather scientifically trained, for that is where we break down; we are slow to recognise that a works chemist should be trained to the pitch of a scientific investigator. It is the want of such men that has given ground for this wearying talk about the raw coal-tar products we export and the refined products we import; and we may double the National Debt in paying South Kensington grants for chemical teaching, we may erect technical schools with the model plant in every parish in the land, but until the British manufacturers realise the true value of the scientific chemist, we shall continue to import refined coal-tar products, and much besides, and shall steadily fall behind in the race for industrial prosperity.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*New Process and Apparatus for Concentrating Sulphuric Acid.* M. M. Gerber. *Monit. Scient.* 41, 366.

See under VII., page 36.

*The F. L. Bartlett Zinc-Lead Process.* Abstract of Report, by E. W. Hawker. *Eng. and Mining J.* 56, 1594.

See under X., page 41.

*A Crucible Furnace for Burning Petroleum.* W. E. Crane. *Eng. and Mining J.*, December 23, 1893, 644.

This furnace is built round as high as the top of the crucible, and 4 or 5 in. larger in diameter. From thence upwards it is built square, and the corners used as described further on. The pot stands on a support about 6 in. high. If it is a furnace running continually, it is immaterial of what substance it is made, or how solid, provided it will withstand the high temperature. If a furnace runs to 12 hours only per day it should be made with as little substance as will withstand the temperature and weight. If made solid, the first heat will take longer, as this support must be thoroughly heated through before the bottom of the pot will heat. After the first heat any support will be all right. Fig. 1 shows an elevation of the furnace, which has been rebuilt from one using grates for coal. A brick bottom is put over the grates to preserve them, but one grate should be taken out and a hole left through the bottom, so that the metal can run through if the pot breaks. Fig. 2 shows a part plan of furnace at the top of the pot. Four pieces should be provided of the shape shown at A in one of these corners, which will rest on top of the pot and in the corner of the furnace, shutting in the products of combustion around the pot below the top. By this means fully 15 per cent. of the fuel will be saved, a much hotter fire secured, and faster work done. A small flue should lead off from the top of this chamber, not over 2½ in. square, either to the chimney or to a heater for heating the air, or to other system of economising the heat from waste gases. When the waste heat is utilised, this construction is essential in melting alloys, especially where spelter or zinc is used, as the fumes would coat over or fill up any economiser. By closing the space at the top of the pot the fumes from the alloys could be carried off through a separate flue. This flue should have from 30 in. to 40 in. area. The burner would probably be an air burner, with as low a pressure as possible. Some burners work nicely with as low as 6-oz. pressure. All of the air for combustion should be supplied by the blower. With an air burner at high temperatures there is usually a deposit of carbon. This can be prevented by introducing a small jet of steam, preferably superheated. As a general thing this will be

Fig. 1.

Fig. 2.

CRUCIBLE FURNACE FOR BURNING PETROLEUM.

found to cause more annoyance than that of removing the deposited carbon. The steam will have a tendency to lengthen the flame, and as a consequence the heat will be less intense, more of the heat passing off into the flame.

There should be a good draught to take off fumes when melting alloys, which smoke a good deal; but the draught from the products of combustion should be light. For the support for the crucible in furnaces running 10 hours per day, I have found an old pot cut off at the right length and turned bottom up to be as good as anything tried. The pieces to shut off at the top of the pot should be made of crucible stock and well seasoned.

### PATENTS.

*An Improved Oil Separator for Use with Steam Boiler Feed-water Apparatus.* J. S. McDougall, Didsbury. Eng. Pat. 21,867, November 30, 1892.

ONE shape of this apparatus, which is more particularly intended for the extraction of oil from the water passing through condensers for repeated use in boilers, is represented in the illustration.

It consists of a flat casing of pyramidal shape, provided with a number of inclined surfaces, as shown below in

IMPROVED OIL SEPARATOR.

section, which reach with their lower ends between other short inclined partitions attached to the bottom of the casing. The impure water enters near the bottom at one side of the chamber, and on passing over the several partitions in an undulatory fashion, parts with the admixed oil and leaves at the other end of the chamber in a purified state. The oil rises to the top of the chamber, where it can be withdrawn at intervals. Other impurities left on the bottom of the chamber can be taken out through special cleaning holes.—B.

*Process of Enriching Milk and Producing Cream and Butter.* M. Julien, sen., and A. Brin, London. Eng. Pat. 22,115, December 2, 1892.

See under XV111., page 55.

*Improved Application of Aluminium and its Alloys.* W. R. Taylor, Rochester. Eng. Pat. 22,843, December 12, 1892.

See under X., page 42.

*An Improved Connection or Coupling for Use in Conjunction with Cylinders, Flasks, and Vessels containing Gases and Fluids under High Pressure.* The Manchester Oxygen (Brin's Patent) Co., Limited, and W. M. Jackson, Manchester. Eng. Pat. 23,837, December 24, 1892.

The coupling is shown in sectional elevation and plan by Figs. 1 and 2 respectively, while Figs. 3 and 4 are an elevation and plan of the detachable connection C, fitted with the locking sleeve d. This sleeve has a longitudinal slot i, so that it can be slipped over the connection C and the lug e thereon, the thimble e being afterwards screwed on. The wings f of the sleeve d are now inserted in the recessed portions j of the valve fitting A, and then turned round by the capstan heads h, whereby they assume the position shown in Fig. 1, the raised portions f<sup>1</sup> of the sleeve d bearing upon similar raised portions at g<sup>1</sup> and

GAS CYLINDER CONNECTION.

pressing the thimble e into the rubber ring a, which latter ring is inserted in a suitable undercut recess in the fitting A. With this arrangement the pressure in the bore of the valve fitting presses the rubber tightly against the thimble e, and the thimble e is pressed very tightly into the rubber by the arrangements above described; thus an extremely good joint is secured. Various modifications are described and illustrated.—E. G. C.

*Improvements in the Manufacture of Linoleum, Kamptulicon, and other similar Floorcloths, and in the Means employed in such Manufacture.* J. S. Farmer, Salford, and H. L. Storey and I. H. Storey, Lancaster. Eng. Pat. 23,983, December 29, 1892.

See under V., page 33.

*An Improvement in Apparatus for Heating, Evaporating, Condensing, and the like.* A. Normandy and F. Normandy, London. Eng. Pat. 125, January 3, 1893.

THIS is an arrangement for facilitating the cleaning of the tubes of heating coils, by fitting the coil on hinges in a casing provided with a lateral opening, through which the coil may be swung on the removal of the cover. Or the coil may be made to slide along a hinged arm, on which it may be swung through the said opening clear of the casing.—B.

*Improvements in the Method of and Apparatus for Washing Wool and other Fibres.* P. Kelly, Cross Hills, Works. Eng. Pat. 1897, January 28, 1893.

See under V., page 34.

*Improvements in Centrifugal Separators for Cream and Butter.* A. Wahlén, Rainbridge, U.S.A. Eng. Pat. 11,026, June 6, 1893.

See under XVIII. A., page 56.

*Improvements in the Production of Vacuum and Means for that Purpose.* J. Dewar, Cambridge. Eng. Pat. 439, January 9, 1893.

THE aim of this invention is to provide a substitute for the mercurial air pump hitherto used for attaining a high degree of vacuum in closed vessels. For his purpose the inventor fills the vessel to be exhausted with a condensable vapour in such a manner as to entirely exclude the atmospheric air. He then subjects a portion of the vessel, which can be hermetically sealed off from the main body, to a lower degree of temperature than the main vessel, whereby the vapours are condensed, producing a highly vacuous space in the main vessel, the degree of vacuity being in proportion to the lowering of the temperature in the subsidiary vessel. The latter is then hermetically sealed off the main vessel.

The vapours proposed to be used are either those of mercury, iodine, sulphur, or selenium in the case of elementary bodies, or else those from compound volatile inorganic or organic substances.—R.

*Improvements in Apparatus for the Making or Manufacture of Caustic Soda or Caustic Potash, being a Method of Passing the Chlorine and Sodium Gases to the Receiver.* F. W. Petrie, Rochdale. Eng. Pat. 472, January 10, 1893.

See under VII., page 38.

*Improvements in Apparatus for Removing Impurities from Water.* W. Shedlock, Stockwell. Eng. Pat. 1052, January 17, 1893.

THE invention relates particularly to water-purifying apparatus for boilers. A number of sections are arranged inside the boiler, each consisting of two tubes connected at each end by a narrow neck joined by suitable sockets to form the depositing chambers. The feed-water is admitted by a cock and passes through the apparatus, depositing salts and other impurities in the tubes, finally passing out by the orifice into the boiler. The impurities deposited in the apparatus are removed by turning round the plug of the cock, thereby arresting the entrance of the water and allowing steam to enter to blow through the apparatus, whereby the deposited matter is swept out. By giving the plug of the cock a further turn, hot water from the boiler is admitted to the chambers to obviate the formation of a vacuum in the apparatus, which might be caused by feeding in water at a low temperature after steam has been blown through them. Feed-water is now admitted by turning the cock round till it assumes the first position, when the same series of operations is performed. The cock is of special design with numerous parts; it is rotated by a worm and worm-wheel arrangement; suitable screwed connections for the different pipes are formed on the valve casting.—E. G. C.

*Improvements in and Apparatus for the Manufacture of Bleaching Powder.* E. K. Muspratt, Liverpool, A. Carey, and V. C. Driffield, Lancaster. Eng. Pat. 1214, January 19, 1893.

See under VII., page 38.

*Improvements in Apparatus or Vessels for the Continuous Evaporation or Concentration of Liquids.* E. B. Harlock. Eng. Pat. 1708, January 25, 1893.

THIS invention refers to the shape of vessels employed in a series, each constructed with an internal diaphragm or open-mouthed tube along one side, which causes the incoming liquor to descend to the bottom of the vessel, whilst the outflowing liquor is drawn off near the surface.—R.

*Improvements in the Treatment of Cotton Cloths for Filtering Purposes.* H. E. Newton, London. From E. de Haen, List vor Hanover, Germany. Eng. Pat. 1770, January 26, 1893.

See under V., page 34.

*Improvements in Apparatus for Raising Liquids.* M. Macer, Enfield Highway, in the county of Middlesex. Eng. Pat. 1733, January 26, 1893.

THE apparatus is shown in sectional elevation in the accompanying figure. The rising main *a* has a strainer *f* at its lower extremity, and is also provided with a valve box *b*, containing a spherical non-return valve *c*. A jet of steam

APPARATUS FOR RAISING LIQUIDS.

is introduced into the contracted part *h* of the rising main by means of a steam nozzle *g*, thereby forcing the water contained in the tank up the pipe *a*, as in the ordinary form of injector.—E. G. C.

*Improvements in the Extraction of Carbonic Acid from Mineral Carbonates, and in Apparatus therefor.* A. van Berkel, Berlin. Eng. Pat. 2274, February 1, 1893.

See under VII., page 32.

*Improvements in Apparatus for Evaporating and Cooling Liquids.* E. G. Scott, Liverpool, and F. W. Scott, London. Eng. Pat. 2340, February 2, 1893.

THE invention has reference to apparatus for evaporating hot liquids by means of currents of air. The apparatus is shown in sectional elevation by the accompanying figure,

in which *a* is a long vertical column carrying at its upper extremity a cistern *c* with a perforated bottom *d*, and below

EVAPORATING APPARATUS.

resting upon a cistern *b*. The hot liquid is introduced into the cistern *d* and thence falls in fine streams down the pipe *a*, being met by a current of air which enters the column at its base *f* and is discharged at the point *e* by an exhausting fan shown at the side. A pump attached to the lower cistern serves to remove the liquid which collects in *b*. With this arrangement the coolest air traverses first the coolest liquid and *vice versa*.—E. G. C.

*Improvements in Effecting the Protection of Iron and Steel Surfaces, and in the Furnaces employed therein.* F. S. Barff, Kilburn, and G. Bower and A. S. Bower, S. Neots. Eng. Pat. 3304, July 28, 1881. (Reprint.)

See under X., page 41.

*Improvements in the Manufacture of Dough from Cereals and Apparatus therefor.* F. J. Gelinck, Riga. Eng. Pat. 15,067, August 5, 1893.

See under XVIII. A., page 56.

*Improvements in or relating to Apparatus for Drying "Slip" and Evaporating Liquids.* S. Peake, Gillow Heath, near Congleton. Eng. Pat. 15,616, August 17, 1893.

See under VIII., page 39.

*Improvements in Centrifugal Liquid Separators.* C. J. Lundström, D. H. Burrell, and E. J. Burrell, Little Falls, Herkimer, U.S. America. Eng. Pat. 15,843, August 21, 1893.

THE essential points of the patented improvement as applied to cream separators are represented in the accompanying illustrations, in which *A* is the casing, *B*

Fig. 1.

Fig. 2.

IMPROVED CENTRIFUGAL LIQUID SEPARATOR.

the revolving drum supported on the spindle *b*, which passes, near its upper extremity, through bushes *a* and *D*, held to their respective places by means of elastic rings *a'* and *d'* sprung into grooves. The lower end *n* of the spindle is supported on a steel ball resting on a pin screwed into a bush from below. The ball is somewhat

smaller in diameter than the space left in the bush for its reception. When at work it does not thus remain directly under the centre of the spindle, but at a distance therefrom, which causes it to be carried round and kept in constant motion. The rotary drum is fitted with a conical vessel *m*, the lower part of which is intended to retain the coarser impurities contained in the liquid, whilst the radial arms *l* tend to assist the action of the drum. The full milk enters through the centre at *i*, whilst the cream and skim milk leave the vessel separately as indicated.—B.

**Improved Apparatus for Washing Filtering Media.** W. P. Thompson, Liverpool, Manchester, and London. From W. Arnold, Gablenberg, near Stuttgart, Germany. Eng. Pat. 18,122, October 2, 1893.

THE apparatus for washing filtering media, shown in sectional elevation by the accompanying figure, consists of a vessel A divided into two compartments by a vertical partition A', which does not extend right through longitudinally. In the left-hand compartment is an agitating or stirring drum B, driven by the shaft and pulley C, and in the right-hand compartment is a lading apparatus or drum D, provided with a number of scoops *d*, and driven from the lower shaft C by a belt and pulleys. The material to be

APPARATUS FOR WASHING FILTERING MEDIA.

cleansed is placed in the vessel A, which latter is supplied with fresh water by the pipe *a*. The material is thoroughly agitated and washed by the drum B, and the dirty water is caught up by the revolving scoop *d* and emptied between the radial vanes D' of the drum D, escaping by the outlet E on the axle into the hollow trunnion shaft *e* and away. When the filter material has been thoroughly cleansed, the water may be run off and the mass of material removed.

—E. G. C.

## II.—FUEL, GAS, AND LIGHT.

*Gases enclosed in Coal and Coal-Dust.* W. McConnell. Report of Investigation carried out in the Durham Coll. of Science, 1893.

THE author, pursuing the work of Bedson, von Meyer, and others, has examined the gases given off by coal and coal-dust when heated in a vacuum. The samples used in the investigation included the Ryhope coal, which formed the subject of Bedson's inquiry. Particular attention was paid to the nature of the paraffin hydrocarbons obtained in the course of the analysis of the gases extracted from the coal, the results of their explosion, and the observation of the contraction and absorption of carbon dioxide in the usual way, sufficing to arrive at an approximate estimate of the mean number of carbon atoms per molecule, and thus to determine which members of the paraffin series were probably present.

**Ryhope Coal (a gas-coal).**—100 grms. of coal gave off 818 cc. of gas when heated in a vacuum to 100° C., the average composition of the gas being:—Carbon dioxide, 0.72; oxygen, 9.41; olefines, nil; paraffins, 16.91; nitrogen, 72.95 vols. per cent.

The combustible constituents of the first fraction drawn off appeared to contain methane and hydrogen, while those of the last fraction consisted of a mixture of methane and ethane. A further quantity of gas was obtained on powdering the extracted coal and again exhausting. It was distinguished from the former sample by the presence in it of some paraffin higher than ethane, probably propane. When the temperature of extraction was raised to 184° C., indication of the presence of yet higher hydrocarbons was obtained.

**Seaton Delaval Coal.**—This, which is a steam- as distinguished from a gas-coal, differs from the Ryhope coal in the fact that the gases obtained from it consist solely of carbon dioxide, oxygen, and nitrogen, being quite free from hydrocarbons.

**Hebburn Coal.**—This coal liberates so much gas while being worked in the colliery, that the gas is in some cases conveyed to the surface and burnt under the boilers. When examined by the author it was found to evolve 3.56 times its volume of gas, the average composition of which is given below:—Carbon dioxide, 1.5; oxygen, 1.1; paraffins, 78.0; nitrogen, 19.3 vols. per cent.

The paraffins from the coal itself consisted of a mixture of methane and ethane, while the powdered coal and the coal-dust yielded gases containing higher hydrocarbons. The combustible constituent of the gas given off naturally as "blowers," is on the other hand, mainly methane.

**Coal from another Durham Colliery.**—This colliery, which works the Hutton seam, and was some time ago the scene of a disastrous explosion, is not definitely named in the paper. 100 grms. of coal gave 160.9 cc. of gas, which had the following composition:—Carbon dioxide, 1.7; oxygen, 1.1; carbon monoxide, 0.0; olefines, 0.0; paraffins, 88.5; nitrogen, 8.7 vols. per cent.

The portion of the gas recorded above as "paraffins" consisted almost entirely of methane.

The crushed coal and the coal-dust yielded gas which was poorer in combustible constituents than that obtained from the coal itself, but contained higher hydrocarbons than methane.

From the comparison of these results the author arrives at the conclusion that the deeper seams of coal yield coals containing combustible gases and carbon dioxide, and that in passing to the younger seams the proportion of carbon dioxide increases even to the total exclusion of combustible constituents.

Certain subsidiary experiments were made to determine the amount of ethane absorbed by charcoal and coal. It was found that 100 grms. of boxwood charcoal, when saturated with ethane and placed in a vacuum at the ordinary temperature, retained 109.3 cc. of ethane, which it yielded on heating to 100° C. Similarly, 100 grms. of Hebburn coal retained 96.5 cc. of ethane.

The ease with which occluded gases are expelled from coal by diffusion was shown by experiments on Ryhope coal in an atmosphere of hydrogen. From these experiments it was evident that an exchange of gases takes place between the coal and the hydrogen atmosphere, the coal first taking up the hydrogen, which in turn expels nitrogen and a little oxygen from the coal. Then, as the heating is continued, the hydrogen is expelled, and along with it some methane, the proportion of the latter and of the carbon dioxide, increasing as the heating is continued and the pressure reduced.

Experiments on the limiting proportions of an explosive mixture of ethane and oxygen and ethane and air, led to the following conclusions:—

(1.) When mixed with oxygen, a mixture containing 3·3 per cent. of ethane will not explode even under a pressure of nearly 1,300 mm. of mercury; a mixture containing 4·6 per cent. of ethane explodes very slightly under a pressure of 250 mm.; while one of 4·5 explodes at once under a pressure of 350 mm. Mixtures containing more than 8 per cent. of ethane explode too violently to be manageable.

(2.) When mixed with air, a mixture containing 3·8 per cent. of ethane will only explode when the pressure is as high as 1,530 mm., while a 4 per cent. mixture explodes under a pressure of 596 mm.—B. B.

*Heat of Combustion of Coal-Gas, and its Relations to Lighting Power.* M. Agnition. *Comptes rend.* 117, 56—58.

WHEN the calorific power of a given sample of coal-gas (determined by means of Berthelot's bomb, modified for industrial use by Mahler) is compared with its illuminating power, a close connection is found to subsist between the two. As the mean result of experiments with more than 100 specimens of gas of varying degrees of richness, the relationship is found to be given by the rectilinear equation,  $C = 1 \times 352 \cdot 6 + 2280$ , where  $C$  is the heat of combustion, and  $I$  the lighting power in decimal candles, this formula being verified between the limits of 5 and 15 candles. The following table exhibits in more detailed fashion this relationship, the heat of combustion being that of 1 cubic metre of gas at 15° and 760 mm., measured dry, the water vapour produced by combustion being condensed, and the volume supposed constant; and the illuminating power being the light produced (measured in decimal candles) when 100 litres of gas are burnt per hour (1 carcel = 9·6 decimal candles):—

Illumination in Decimal Candles.	Photometric Titre according to the Regulation Photometer.	Heat of Combustion of 1 Cubic Metre of Gas at 15° and 760 mm.  Calories.
15	64	7,569
14·5	66·2	7,392
14	68·5	7,216
13·5	71·1	7,049
13	73·8	6,884
12·5	76·8	6,717
12	80	6,551
11·5	83·1	6,385
11	87·2	6,218
10·5	91·4	6,052
10	96	5,886
9·5	100	5,720
9·14	105	5,563
9	106·6	5,453
8·5	112·9	5,277

Illumination in Decimal Candles.	Photometric Titre according to the Regulation Photometer.	Heat of Combustion of 1 Cubic Metre of Gas at 15° and 760 mm.  Calories.
8	120	5,101
7·5	128	4,924
7	137	4,748
6·5	147·6	4,572
6	160	4,396
5·5	174·5	4,219
5	192	4,043

Since the photometric value of lighting gas varies directly with its calorific power, it would be preferable to use the latter as the means of valuation, because the former varies with the nature of the burner used, and its mode of use. Moreover, valuations on this principle of the quality of coal-gas, are directly applicable when the gas is used as a heating agent or as a source of motive power; accordingly the replacement of the photometer by the calorimetric bomb is recommended.—C. R. A. W.

*The Causes and Prevention of Spontaneous Combustion.* L. Häpke. *Chem. Zeit.* 1893, 17, 916.

THE cause of spontaneous combustion is to be found in the physical and chemical capacities of certain carbonaceous and organic matters, to condense on their surfaces gases and moisture. The amount of gases thus condensed, varies with the chemical nature of the gas, and is also dependent upon the degree of subdivision of the absorbing substances. If the atmospheric oxygen is the gas thus condensed, evolution of heat accompanies the condensation, and if this occurs within a bad conductor of heat, the latter accumulates and eventually gives rise to spontaneous combustion. In the case of fermentable matter, such as hay and tobacco, bacteria frequently initiate the process of spontaneous combustion. In all cases the molecular structure of the substances, the temperature, moisture and pressure of the air, present determinative conditions. The first record of spontaneous combustion observed on an artificially prepared substance was given by Boyle in 1680. Shortly afterwards Homburg discovered another pyrophorus consisting of potassium sulphide, carbon, and alumina. Coal fires due to spontaneous combustion were first observed at Brest (1757) and on board the "Maria" at Kroustadt (1781). In the latter case the fire was found to have originated in a mixture of linseed oil and soot. The explosion of four gunpowder factories within a short space of time in the beginning of this century was caused by spontaneous combustion. Aubert found that finely-ground charcoal placed in a barrel attained a temperature of 75° C. after 15 hours; after 20 hours ignition took place. The charcoal was found to have absorbed oxygen and also a not inconsiderable quantity of water. Liebig (1866) showed the liability to spontaneous combustion of coal containing pyrites. Abel and Percy (1876) confirmed this observation and recommended frequent observations of the temperature. Air shafts through the masses of coal on board ship, were found to be actually favourable to spontaneous ignition, and of four vessels carrying coal to India, three were thus well ventilated, but they were all lost through spontaneous combustion taking place; the fourth, having no such ventilation whatever, reached its destination safely. Experiments on the extinction of fires on board ship with liquid carbonic acid proved unsuccessful. Coals for export by water, ought to be carefully selected as to quality, and means should be adopted for preventing the coal from being moved about and crushed through the rolling of the vessel. Spontaneous combustion of coal stacks not seldom takes place, where great masses of coal are stacked. The height of a coal stack should never exceed 2·5 m. The

often asserted spontaneous combustion of wet cotton is very improbable, but a spark getting into a bale will smoulder for a long time, and the fire will then doubtless be put down to spontaneous combustion. Greasy cotton is, however, exceedingly dangerous, most fatty oils absorbing large quantities of oxygen with evolution of much heat. In cotton mills the time elapsing between Saturday afternoon and Monday morning particularly calls for watchfulness, as during this time all those materials inclining to spontaneous combustion lie uncontrolled. The few cases of spontaneous combustion of wool, flax, jute, or oakum, were also due to these materials being impregnated with oil, varnish, or certain dyes. Heavily weighted silk is also liable to spontaneous combustion, one case being recorded by Perroz, and another having occurred on board ship. Spontaneous ignition of hay stacks, although frequently disputed, is an undoubted fact, which was experimentally established by Ranko at the instigation of Liebig. The heat in the stack was found to rise to 300° C., the hay being converted into a voluminous mass of carbon. Cohn showed that fermentation caused by bacteria is responsible for such occurrences, which in Holland are prevented by throwing common salt between strata of the hay in erecting the stacks. For the same reason the stacks are built with an air shaft in the centre. Fermentation is also frequently the cause of the spontaneous combustion of tobacco. Also a case of spontaneous combustion of lupulin has been lately observed. The attempt to indicate the danger of spontaneous combustion by means of electric signals has not been successful so far. A lately invented tire indicator, which utilises the expansion of air by heat, and which can be connected with any electric or telephonic circuit, may be found very useful.—C. O. W.

*An Apparatus and Method for Determining the Density of Gases suitable for Industrial Purposes.* M. Meslans. *Comptes rend.* 117, 386.

See under XXIII., page 64.

*Manufacture of Oxygen by means of the Dissociation of Plumbate of Lime.* H. Le Chatelier. *Comptes rend.* 117, 109—110.

PLUMBATE of lime,  $\text{PbO}_2 \cdot 2\text{CaO}$ , breaks up on heating, forming lead oxide, and quicklime, and evolving oxygen, whilst the residual solid on exposure to air at a suitable temperature takes up oxygen again, reproducing the original compound. The manufacture of oxygen in this way (Kastner's process) has the advantage that the reabsorption of oxygen is more rapid than in the barium dioxide processes, whilst it is not necessary to dry the air employed, nor to remove carbon dioxide therefrom. On the other hand, a perceptibly higher temperature is requisite for the decomposition, viz., about 900° instead of 700° under a pressure of  $\frac{1}{10}$  atmosphere, which causes more rapid destruction of the iron retorts employed, as well as greater fuel consumption. The following values represent the oxygen tensions of plumbate of lime for various temperatures:—

Temperature.	Pressure in Mm. of Mercury.	Temperature.	Pressure in Mm. of Mercury.
880	47	1060	557
940	112	1070	570
950	117	1100	940
1020	350	1110	1040

—C. R. A. W.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Chrysene.* E. Bamberger and F. Chattaway. *Ber.* 26, 1893, 1745—1751.

THE authors have found that chryseneic acid obtained from chrysoquinone or chrysoketone may be decarboxylated by subjecting it to distillation with lime under greatly diminished pressure and at as low a temperature as possible. The greater part is converted into chrysoketone; besides this, however, a hydrocarbon,  $\text{C}_{16}\text{H}_{12}$ , is obtained. It is isolated from the ketone by distillation with steam, and forms white, lustrous laminae, melting at 102°—102.5°. It is identical with  $\beta$ -phenyl-naphthalene obtained from phenyl-glycol and from naphthalene. Thus the formula—

assigned to chrysene has been confirmed both by synthesis and analysis, chryseneic acid being the carboxylic acid of  $\beta$ -phenyl-naphthalene, probably  $\beta$ -phenyl- $\alpha$ -naphthoic acid—

It is also shown that the product obtained by Graebe and Schmidt from chrysoquinone by distillation with soda lime is identical with the  $\beta$ -phenyl-naphthalene obtained from chryseneic acid.—D. B.

*Picene.* E. Bamberger and F. Chattaway. *Ber.* 26, 1893, 1751—1754.

PICENE, which is the only well-defined, high molecular coal-tar hydrocarbon, melts at 350° (uncorr.) and at 364° (corr.), having a higher melting point than any other known hydrocarbon. It yields a quinone,  $\text{C}_{20}\text{H}_{10}(\text{CO})_2$ , and possesses all the properties characteristic of an ortho-diketone. It shows the carbidine, azine, and Bamberger reactions, dissolves in sodium bisulphite, and yields picene ketone when distilled with lead oxide. The latter corresponds with diphenylene ketone, retene ketone, and chrysoketone, has the formula  $\text{C}_{20}\text{H}_{14}\text{CO}$ , and on reduction gives rise to the formation of picene fluorene alcohol,  $\text{CH}(\text{C}_{10}\text{H}_7)_2 \cdot \text{OH}$ , and picene fluorene,  $\text{CH}_2(\text{C}_{10}\text{H}_7)_2$ . When fused with potash, a monobasic acid,  $\text{C}_{20}\text{H}_{15} \cdot \text{COOH}$  is obtained, which closely resembles chryseneic acid. As this substance on heating with lime yields carbonic anhydride and a hydrocarbon  $\text{C}_{20}\text{H}_{14}$ , which is identical with  $\beta$ - $\beta$ -dinaphthyl, picenic acid must be  $\beta$ -dinaphthyl-naphthoic acid—

and picene itself  $\beta$ - $\beta$ -dinaphthylethylene—

Picene is therefore the phenanthrene of the naphthalene series, being related to phenanthrene, retene, and chrysene, as illustrated by the formulae—

—D. B.

*The Colour of Acenaphthylene.* C. Graebe. *Ber.* 26, 1893, 2354—2355.

FROM the author's investigations it appears that acenaphthylene is a coloured hydrocarbon, all attempts to decolorise it having given negative results. Like diphenylene ethane

a red hydro-carbon (this Journal, 1893, 187), acenaphthylene yields a colourless bromide, and on dissolving the latter in toluen and heating with sodium, the colourless solution rapidly changes to yellow. As both acenaphthene and acenaphthylene bromide are colourless, the author concludes that for the coloration of acenaphthylene the group  $>C=C<$  is essential, in addition to which the groups replacing hydrogen in ethylene are of influence, seeing that both diphenylethane and tetraphenylethane are colourless.

Armstrong has extended his "quinonoid" theory (Proc. Chem. Soc. 1892, 192) to bidiphenylene ethane; the author, however, considers that his formula—

is more probable than that advocated by Armstrong.—D. B.

#### IV.—COLOURING MATTERS AND DYES.

*Saffron and its Adulterants.* E. Vinassa. Archiv. der Pharm. 1892. 231, 353; Dingl. Polyt. J. 290, 47.

See under XXIII., page 71.

*Azo Derivatives of Hydroquinone.* O. N. Witt and E. S. Johnson. Ber. 1893, 26, 1908—1912.

On mixing solutions of a diazo-compound and hydroquinone, reaction occurs but no azo-colouring matter is deposited owing to the great reducing power of hydroquinone; the latter thus behaves similarly to pyrocatechol in this respect. Azo-compounds are, however, readily obtained by combining the diazo-compound with benzoylhydroquinone and subsequently eliminating the benzoyl-group. *Benzoylhydroquinone*,  $\text{C}_6\text{H}_4(\text{OH})\text{OCOC}_6\text{H}_5$ , is prepared by stirring benzoyl chloride into a caustic soda solution of hydroquinone; 100 grms. of the latter give 120—130 grms. of the benzoyl derivative if a mechanical stirrer be used, otherwise a much smaller yield is obtained. The deposited product is extracted with caustic soda and crystallised from alcohol; it finally melts at 162—163°. The concentrated diazo-solution is added to the calculated quantity of benzoylhydroquinone dissolved in 20—25 parts of alcohol; 25 per cent. caustic soda is then added until the colouring matter begins to separate. The weight of the latter obtained is usually about equal to that of the benzoyl-derivative employed. The benzoyl group is removed from the azo-compound by adding concentrated potash to its alcoholic solution, diluting with water, and precipitating with hydrochloric acid. In this way the aniline, *p*-toluidine, *p*-nitraniline, tolidine, and sulphanilic acid derivatives of azohydroquinone and their benzoyl derivatives, were prepared. The benzoyl derivatives are mostly yellow, whilst the unsubstituted compounds are mostly red or blue; nearly all crystallise well.—W. J. P.

#### *Nitrohydroxy- and Nitro-amido-azo Compounds.*

E. Tauber. Ber. 1893, 26, 1872—1876.

NITROHYDROXYAZOSULPHONIC acids are, as a rule, completely converted into the corresponding nitro-amido-azosulphonic acids by heating for 16 hours at 150°—160° C. with 20—25 per cent. ammonia. The use of so costly and undesirable a material as orthonitrophenol in the manufacture of nitrohydroxyazosulphonic acids may be avoided by nitrating the corresponding hydroxyazosulphonic acid; the latter is dissolved in concentrated sulphuric acid and the calculated quantity of potassium nitrate added at 10°—20°. On pouring the product into water the nitro-derivative separates, and may be crystallised from 10 per cent. hydrochloric acid. The above processes give excellent results in a number of cases.

*m*-Nitro-*p*-hydroxyazobenzene para- and meta-sulphonic acids were prepared by nitrating the corresponding hydroxyazobenzenesulphonic acids and were then converted

into the amido-derivatives by heating with ammonia. *m*-Nitro-*p*-amidoazobenzenesulphonic acid yields very beautiful azo-colouring matters by diazotisation. The homologous compounds derived from the toluidinesulphonic acids are very similar to those obtained from the aniline acids.

—W. J. P.

*Hydroxy-Derivatives of Anthraquinolinequinone.* C. Graebe and A. Philips. Annalen, 276, 21—35.

*Hydroxyanthraquinolinequinone*—

is prepared from the amide of Alizarin blue (amidohydroxyanthraquinolinequinone); this (2 grms.) is dissolved in concentrated sulphuric acid (16 cc.), water (4 cc.) is added, and the whole cooled to 0°; sodium nitrite (2.5 to 3 grms.) is gradually introduced and the product poured into boiling alcohol (200 cc.) and kept boiling for 15 minutes. The product is almost insoluble in water; it forms brick-red prisms (melting point 208°), is soluble in alcohol, forms a violet solution in alkali and a yellowish-brown solution in strong sulphuric acid. *Trihydroxyanthraquinolinequinone* was obtained from the portion of crude Alizarin green which is insoluble in nitrobenzene (compare also Schmidt and Gattermann, this Journal, 1891, 1003). It crystallises in scales having a coppery lustre, dissolves in sulphuric acid with a bluish-violet coloration, and in caustic alkalis to a blue solution. *Tetrahydroxyanthraquinolinequinone* (Dihydroxyalizarin blue)—

occurs in small quantity in commercial "Alizarin green" and in "Alizarin indigo blue," and is identical with the substance which Schmidt and Gattermann obtained by nitrating quinalizarin and conversion of the nitro product into the corresponding quinoline derivative. It forms blue solutions in alkalis and in sulphuric acid. *Pentahydroxyanthraquinolinequinone*—

forms the constituent of "Alizarin indigo blue" which is soluble in nitrobenzene; it forms an indigo blue crystalline mass, and is soluble in alkalis and in sulphuric acid, forming blue solutions.

"Alizarin blue-green" contains a monosulphonic acid of Hydroxyalizarin blue, as stated by Schmidt and Gattermann, whilst an isomeric acid is contained in "Alizarin green." "Alizarin indigo blue" is a mixture of pentahydroxyanthraquinolinequinone with some tetrahydroxyanthraquinolinequinone and a sulphonic acid derived from the latter.

The higher hydroxy-derivatives of "Alizarin blue" yield *quinolinic acid* on oxidation with nitric acid.—A. K. M.

*The Theory of Mordant Dyes.* C. Liebermann. Ber. 1893, 26, 1574—1578.

It has been recently pointed out by the author, in conjunction with Bistrzycki, that not only are numerous derivatives of opianic acid coloured, but that some of them, such as tetramethoxydiphthalyl and bisdimethoxymetindolone, when heated with concentrated sulphuric acid, yield yellow colouring matters which unite with mordants. The view then expressed that the action of the sulphuric acid consisted in the elimination of the methyl groups is confirmed by the formation of the same products by the action of hydriodic acid. Thus the product obtained from tetramethoxydiphthalyl and hydriodic acid is tetrahydroxydiphthalyl—

previously described by Goldschmidt and Egger (Monatsh. 12, 61). This substance affords confirmation of the view advocated by the author and Kostanecki that the property of forming coloured derivatives with mordants depends upon the presence of two hydroxyl groups in the ortho-position to one another. Following up this view, he suggests that combination with the polyval metal (e.g., Al or  $\text{Fe.Fe}$ ) will only be possible when the hydroxyl groups of the colouring matter are in the ortho-position, and the formulae of alizarin red and alizarin violet may be—

According to this view, the metal of the mordant forms a link of a pentatomic (Al) or hexatomic ( $\text{Fe.Fe}$ ) ring, and this would account for some hitherto unexplained properties of certain mordant dyes, such as their great stability and the fact that the ordinary properties of the metal are frequently masked.—A. K. M.

*$\alpha$ - and  $\beta$ -Naphthalene Indigo.* H. Wiechelhans. Ber. 1893, 26, 2547—2550.

NAPHTHALENE indigo may be obtained as follows:—Anhydrous sodium acetate (50 parts), chloroacetic acid (16 parts), and  $\alpha$ - or  $\beta$ -naphthylamine (24 parts) are fused together. At about  $120^\circ$  the mixture froths strongly, and at about  $180^\circ$  it settles down again and becomes nearly dry. Caustic potash (50 parts) is then added, the temperature is raised to about  $290^\circ$ , and the operation stopped when the vapours become greenish and when a sample introduced into hot water and agitated with air, yields a green precipitate. The product, after purification, has a composition agreeing with the formula,  $\text{C}_{24}\text{H}_{14}\text{N}_2\text{O}_2$ . Both the  $\alpha$ - and  $\beta$ -compounds are obtained as green powders which exhibit a copper lustre; they are soluble in aniline, from which they can be crystallised,  $\alpha$ -naphthalene indigo forming blackish-violet needles, and  $\beta$ -naphthalene indigo bluish crystals. The following table shows some of their properties compared with those of benzene indigo:—

	Benzene Indigo.	$\alpha$ -Naphthalene Indigo.	$\beta$ -Naphthalene Indigo.
Reduction product in solution.	Yellow	Orange	Red
Vapour.....	Red	Violet	Blue
Solution in aniline.....	Red	..	Blue-green to blue.
Solution in chloroform, benzene, glacial acetic acid, &c.	Violet to blue.	Blue	
Sulphonic acid in aqueous solution.	Blue	Blue on boiling; blue-green cold.	Blue-green
Sulphonic acid on wool and silk.	Blue	Blue to green	Green
Cotton, dyed.....	Blue	Blue to green	Green

The constitutional formulae of  $\alpha$ - and  $\beta$ -naphthalene indigo are probably—

*Naphthyl Red and Magdala Red.* O. Fischer and E. Hepp. Ber. 1893, 26, 2235—2236.

THE authors have recently shown (this Journal, 1893, 671) that the Mauveines and Indazines must be regarded as symmetrical Indulines, and they have also proved Naphthyl violet and Naphthyl blue to have a like symmetrical constitution. This was shown by the formation of Naphthyl blue by an "inner" condensation of benzene-azophenyl- $\alpha$ -naphthylamine. Applying this reaction to other azo-compounds, the authors find that a new dyestuff

*Naphthyl red*—is formed when benzene-azo- $\alpha$ -naphthylamine is heated with phenol, whilst *Magdala red* is produced when amido-azonaphthalene is heated with phenol. Naphthyl red bears a striking resemblance to Magdala red; its relationship to Naphthyl violet, Naphthyl blue, and Magdala red is shown in the following formulae:—

Naphthyl red.

Naphthyl violet.

Naphthyl blue.

Magdala red.

—A. K. M.

*Action of Alkalis on Paranitrotoluene and its Sulphonic Acid.* O. Fischer and E. Hepp. Ber. 26, 2231—2234.

KLINGEN obtained a red amorphous substance (Ber. 16, 941) on heating *p*-nitrotoluene with alkalis, and this was further investigated by Bender and Schultz (Ber. 19, 3234); this Journal, 1887, 817), who showed it to have a composition agreeing with that of azoxystilbene. By the action of alkalis on *p*-nitrotoluene-*o*-sulphonic acid, Walter obtained the dyestuff *Sun yellow*, whilst Bender obtained *Mikado brown* and *Mikado orange*, but the constitution of these dyes is not yet established. By modifying the conditions of the experiment, the authors have obtained certain intermediate products from paranitrotoluene, by heating it with a solution of caustic soda in methylalcohol, namely, *paradinitro-dibenzyl*, *paradinitrostilbene*, and *paradinitrosostilbene*. The last substance is the main product, and the authors assign to it the formula—

Similarly from paranitrotoluene-orthosulphonic acid, the disulphonic acid of *p*-dinitrosostilbene is obtained, but is

only formed when a concentrated soda solution is employed. Its sodium salt forms a dyestuff and is readily soluble in 10 parts of hot water. When a more dilute solution of soda is used, the commercial product known as *Sun yellow* is produced.—A. K. M.

*Oxidation of Chloroform by Chromic Acid, and the Preparation of Carbonyl Chloride (Phosgene) from Carbon Tetrachloride.* H. Erdmann. Ber. 26, 1990.

See under XX., page 65.

*The Action of Acid Chlorides on Nitrosodimethylaniline.* P. Ehrlich and G. Cohn. Ber. 26, 1756—1757.

Acid chlorides, such as acetyl chloride, benzoyl chloride, benzene sulphochloride, *m*-nitrobenzene sulphochloride, carbonyl chloride, and chlorocarbonic ether react very readily with nitrosodimethylaniline, nitrosotetramethyl-*m*-phenylene diamine, and nitrosodiethyl-*m*-amidophenol. The combination is best performed by mixing benzene solutions of the components. The compound from benzoyl chloride and nitrosodimethylaniline is a slightly yellowish precipitate, which, after well washing with benzene and drying in a vacuum desiccator, is tolerably stable. It dissolves easily in water, alcohol, and acetic acid, slightly in benzene and ether, and is insoluble in petroleum ether. It melts at 92° C. with decomposition, has a bitter taste, and does not give Liebermann's reaction for nitroso compounds. Zinc dust, even in the cold, gives dimethyl-*p*-phenylene diamine, and picric acid or mercury, platinum or gold chloride, all precipitate yellowish double salts. According to analysis the substance has the composition  $C_{15}H_{15}N_3O_2Cl$ , from which it would appear to be an addition product of equal molecules of nitrosodimethylaniline and benzoyl chloride. Its properties, however, do not accord with this view, as it reacts much more energetically than nitrosodimethylaniline or even chloroquinone-imide with amines and phenols. The formation of Toluylene blue takes place instantaneously by mixing alcoholic solutions of toluylene diamine and of the benzoyl compound and other amines, such as dimethylaniline,  $\alpha$ - and  $\beta$ -naphthylamine and tetrahydro- $\alpha$ -naphthylamine, or phenols, such as phenol, resorcinol, pyrogallol, phloroglucinol, dimethyl-*m*-amidophenol,  $\alpha$ - and  $\beta$ -naphthol and *o*-hydroxyquinoline react equally readily, forming the corresponding indanines and indophenols. The constitution is represented by one of the following formulae, of which II. appears to be the more probable:—

Referring to the great readiness with which the substance reacts, the authors call attention to a compound first obtained by Krause (Ber. 12, 47) by treating dichloroquinone di-imide with dry hydrochloric acid. They have obtained it as a white powder having the formula—

and state that it reacts much more readily than the mother substance with amines and phenols.—T. A. L.

*Relation between the Safranines and Indulines.*

O. Fischer and E. Hepp. Ber. 1893, 26, 1655—1657.

In their previous paper (Ber. 26, 1194; this Journal, 1892, 671) the authors showed that the mauveines are to be regarded as indulines, whereas they were hitherto classed

as safranines, and as the mauveines may be considered to be formed by a phenylation of the safranines, the action of aniline on the simplest safranine was investigated. It is well known that safranine salts when heated with aniline yield colouring matters of the induline type, but up to the present no product has been obtained identical with any induline of the amido-azobenzene melt. The authors have succeeded in obtaining and identifying a known induline by this process. Starting with the simplest safranine (Nietzki and Otto, Ber. 21, 1590; this Journal, 1888, 497), which was obtained by removing the amido group from phenosafranine by diazotisation in alcohol in presence of hydrochloric acid, a well-crystallised hydrochloride was obtained of the formula  $C_{18}H_{14}N_3Cl$ , which the authors call *aposafranine*. When this salt is heated with 2½ times its weight of aniline for about three hours on the water-bath, a test dissolved in concentrated sulphuric acid no longer gives a greenish-brown colour, but a reddish-violet. The melt is extracted with benzene, which removes a small quantity of phenylinduline melting at 231° C. The residue consists principally of the hydrochloride of an induline,  $C_{18}H_{13}N_3$ , which can be purified by repeated crystallisation from alcohol containing some hydrochloric acid. The salt forms shining greenish prisms, which dissolve in concentrated or dilute mineral acids with a reddish-violet, and in acetic acid or in water with a yellowish shade. When heated with dilute sulphuric acid under pressure, the substance yields benzene-indone hydrate, and its constitution is expressed by the following formula:—

This shows it to be the simplest induline. When heated with aniline to 140°—150° C. it is converted into phenylinduline, and as this latter compound has also been obtained from azophenine and from the amidophenylinduline (Annalen, 262, 247 and 256; this Journal, 1891, 457) of the amido-azobenzene melt, it is thus shown that the safranines are converted into indulines by treatment with aniline. This is in accordance with the observation that has been made in the amido-azobenzene melt, that safranines are always formed at the commencement of the operation and disappear in the later stages. Assuming that the safranines are ammonium bases, the conversion of aposafranine into benzene-induline takes place according to the following equation:—

The elimination of hydrochloric acid from the safranine molecule is simultaneously accompanied by a change from the ortho to the para quinonoid form.—T. A. L.

PATENTS.

*Improvements in the Recovery of Iron from the Ferruginous Residue left in the Production of Aniline Bases.* S. S. Bromhead. From Lundschoff and Meyers, Grönan, Germany. Eng. Pat. 23,639, December 22, 1892.

See under X., page 42.

*The Manufacture or Production of New Colouring Matters.* H. E. Newton, London. From the "Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 558, January 10, 1893.

In Ger. Pat. 22,714 a process is described for obtaining colouring matters by combining diazo-compounds with chrysoidines, and the present invention is an extension of the method there mentioned. The patentees have discovered

that valuable colouring matters, as regards fastness to light and fulling, are produced by combining the diazo-compounds of aromatic amidohydroxy-carboxylic acids with *m*-phenylene or *m*-tolylene diamine and acting on the resulting chrysoidine compounds with a diazotised amine or amidazo-compound, &c. The following amidohydroxy-carboxylic acids are suitable for this invention:—*o*-amidosalicylic acid ( $\text{C}_6\text{H}_3(\text{OH})\text{NH}_2 = 1.2.6$ ), *p*-amidosalicylic acid ( $\text{C}_6\text{H}_3(\text{OH})\text{NH}_2 = 1.2.4$ ), amido-*p*-hydroxybenzoic acid (obtained from *p*-hydroxybenzoic acid by nitration and reduction), amido-*o*-hydroxy-*m*-toluic acid, amido-*o*-hydroxy-*p*-toluic acid, amido-*m*-hydroxy-*o*-toluic acid, or the sulphonic derivatives of these acids. The following is an instance of several examples given in the specification. The diazo-compound from *p*-amidosalicylic acid, corresponding to 10 kilos. of sodium nitrite, is added to a solution containing the corresponding quantity of *m*-phenylene diamine. After standing some hours or adding sodium acetate and heating, the intermediate compound separates out as a granular mass having the formula—

It is dissolved in water containing 32 kilos. of sodium carbonate, and an amount of diazotised naphthionie acid, corresponding to 10 kilos. of sodium nitrite together with a little water, is slowly added. The formation of the dyestuff is completed by heating, and after salting out and drying, it forms a black powder easily soluble in hot water. It has the following formula:—

A large number of possible combinations are mentioned and the colours they produce on un mordanted wool. These are chiefly various shades of brown.—T. A. L.

#### *Production of Orange Colouring Matters or Dyes.* T. R. Shillito, London. From J. R. Geigy and Co., Basle, Switzerland. Eng. Pat. 788, January 13, 1893.

These colouring matters are produced by heating together benzidine or its homologues and derivatives with *p*-nitrotoluene sulphonic acid in presence of caustic alkali. The following substances may be employed:—Benzidine, diamidophenyltolyl, tolidine, benzidine sulphone, diamidophenyltolyl sulphone, tolidine sulphone, diamidodiphenylene oxide, diamidodiphenylene oxide, diamidocarbazol, diamidostilbene, the ethers of diamidodiphenol, hydroxy-diamidodiphenyl, hydroxydiamidophenyltolyl, and the mono- and disulphonic acids of these compounds. A colouring matter which dyes un mordanted cotton orange is obtained by dissolving 14 kilos. of sodium benzidine sulphone disulphonate and 17 kilos. of *p*-nitrotoluene sulphonic acid in 100 litres of boiling water, and adding 15 kilos. of caustic soda lye of 40° B. The whole is then boiled for about half an hour, and the dyestuff is extracted by boiling with water, and is salted out from this solution. It dissolves readily in water with an orange colour.

—T. A. L.

#### *The Production or Manufacture of Derivatives of Betanaphthohydroquinone or Betanaphthoquinone, and of Colouring Matters therefrom.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 825, January 13, 1893.

By acting with an aqueous solution of sulphurous acid on  $\beta$ -naphthoquinone it is converted into 1,2-dihydroxy-naphthalene ( $\beta$ -naphthohydroquinone). If instead of using sulphurous acid, soluble acid sulphites such as sodium bisulphite be employed, the product of the reaction is 1,2,4-dihydroxy-naphthalene sulphonic acid. The following method is given for the production of this acid:—10 kilos. of  $\beta$ -naphthoquinone "in the form of a paste

containing 30 per cent. of pure quinone" are gradually added to 30 kilos. of a sodium bisulphite solution of sp. gr. 1.1. When the quinone is completely dissolved, the mixture is allowed to stand for several hours, and after filtration is mixed with a concentrated solution of 7.5 kilos. of potassium chloride. The potassium salt separates out, and can be purified by recrystallisation from a solution of sodium bisulphite. The acid so formed can be employed as a photographic developer, and is said to be particularly useful for instantaneous photography. By means of suitable oxidising agents, such as nitrous acid, it can be converted into the corresponding  $\beta$ -naphthoquinone sulphonic acid. By substituting sodium thiosulphate for the bisulphite, a well characterised derivative of 1,2-dihydroxy-naphthalene containing sulphur is produced as follows:—1.6 kilos. of  $\beta$ -naphthoquinone are mixed with 10 litres of water, a solution of 2.5 kilos. of sodium thiosulphate in 10 litres of water is then added, and subsequently 3 kilos. of 20 per cent. acetic acid. After filtration, the addition of potassium chloride precipitates the potassium salt of an acid having the formula  $\text{C}_{10}\text{H}_6(\text{OH})_2(\text{S} \cdot \text{SO}_3\text{K})$ . When the aqueous solution is treated with alkalis it turns reddish-violet. On reduction with zinc dust in presence of acids it forms the mercaptan,  $\text{C}_{10}\text{H}_6(\text{OH})_2\text{SH}$ , which crystallises from hot water in yellowish needles. The sulphonic acid group in the 1,2,4-dihydroxy-naphthalene sulphonic acid is easily displaced, and by reacting on it with nitrosodimethylaniline in presence of thiosulphates, a product having the following formula results:—

The quantities given for the preparation of a dyestuff of this class are:—27.5 kilos. of potassium (1.2.4) dihydroxy-naphthalene sulphate are dissolved together with 50 kilos. of sodium thiosulphate in 1,500 litres of water. A concentrated solution of 32 kilos. of nitro-*o*-methylbenzylaniline sodium sulphate acidified with 36 kilos. of a 33 per cent. acetic acid is then added and the mixture is boiled until there is no longer any increase in the separation of the dyestuff. This is then filtered off and dried. It gives pure and bright blue shades on wool mordanted with chromium salts. The shades are fast to fulling and light, and are said to be even superior to alizarin dyestuffs. The colouring matters can also be used for printing on cotton or wool.—T. A. L.

#### *Manufacture of Blue Colouring Matters.* O. Imray, London. From "The Society of Chemical Industry in Basle," Basle, Switzerland. Eng. Pat. 957, January 16, 1893.

THESE dyestuffs are triphenylmethane derivatives and are obtained by condensing mono-methyl- and mono-ethyl-*o*-toluidine with dichlorobenzaldehyde and oxidising the leuco bases so obtained. About 60 kilos. of methyl-*o*-toluidine, 44 kilos. of dichlorobenzaldehyde, 60 kilos. of alcohol, and 25 kilos. of sulphuric acid are heated for 24 hours on the water-bath in an enamelled vessel. The mixture is then saturated with soda lye, distilled with steam, and the leuco base remaining behind is washed and dried. In order to convert it into a colouring matter 30 kilos. are dissolved in 400 kilos. of hydrochloric acid and 1,500 litres of water and oxidised by means of lead peroxide paste. The colouring matter is then precipitated as zinc chloride double salt, and can be purified by re-dissolving in water. The shades produced on wool and silk, or on cotton mordanted with tannin and tartar emetic, are greenish-blue of great intensity.—T. A. L.

*Manufacture of Monosulphonated Anthracene Acid by the Direct Sulphonation of Anthracene.* J. Murray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis" and Dr. Chapuis, Paris, France. Eng. Pat. 1280, January 20, 1893.

THE only method hitherto known for the production of a monosulphonic acid of anthracene was by reducing the sodium salt of anthraquinone sulphonie acid. By sulphonating anthracene with sulphuric acid of 66° B. at 100° C. only disulphonic acids are obtained, whereas by using an acid of 53° or 54° B. up to 60 per cent. of the anthracene employed is converted into monosulphonic acid. At the same time a small quantity of anthracene is unattacked, and the  $\alpha$ -,  $\beta$ -, and  $\gamma$ -disulphonic acids are also produced. The method of preparation is as follows:—100 kilos. of pure anthracene and 200 kilos. of sulphuric acid of 53° B. are heated for several hours to 120°—135° C. until the anthracene has disappeared. The melt is then poured into 1,000 litres of boiling water, neutralised with sodium carbonate, and left to crystallise. The sodium salt is very sparingly soluble in cold water and separates out almost completely. The properties of the salts of the acid thus produced are identical with those of the acid obtained by reducing anthraquinone sodium sulphonate. By oxidising the acid with chromic or nitric acid it is converted into anthraquinone monosulphonic acid, which, on fusion with soda, gives an almost quantitative yield of alizarin. The mother-liquor obtained as above, after separating the monosulphonic acid, contains disulphonic acids. Certain of these, when heated under pressure with hydrochloric acid, are hydrolysed, yielding anthracene monosulphonic acid or anthracene, whilst the  $\alpha$ - and  $\beta$ -anthracene disulphonic acids are not acted on. A small quantity of  $\gamma$ -disulphonic acid is also produced. These acids are converted into their barium salts, and the salt of the  $\beta$ -acid can be extracted by means of hot water. This acid, which hitherto has not been described, gives a barium salt having the composition  $C_{14}H_8(SO_3)_2Ba \cdot 4H_2O$ , soluble in water at 100° C. A litre of cold water dissolves 9 grms., and when dried in a desiccator it loses  $2H_2O$ . When heated to 110°—120° C. it loses  $4H_2O$ , but absorbs  $2H_2O$  on exposure to the air. The sodium, calcium, and magnesium salts are easily soluble, the lead salt is sparingly so. The acid, when oxidised by nitric or chromic acid, gives anthraquinone- $\beta$ -disulphonic acid, which, on fusion, yields pure anthrapurpurin, giving a tri-acetyl derivative melting at 222° C.—T. A. L.

*The Manufacture or Production of Azo Colouring Matters.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 1851, January 27, 1893.

COLORING matters which produce dark or black shades on unmordanted wool are chiefly obtained by combining the sulphonic acids of a diazotised amido-azo compound with naphthols, dihydroxynaphthalenes or their sulphonic acids, *m*-phenylene diamine, its alkyl or phenyl derivatives,  $\alpha$ - or  $\beta$ -naphthylamine or with their alkyl derivatives. In place of these it is proposed to use, according to the present specification, the  $\alpha$ -naphthylamine sulphonic acid ( $1.8$ )  $C_{10}H_6 \cdot NH_2 \cdot SO_3H$ . The colouring matters are said to produce deep shades on unmordanted wool from a neutral or weak acetic acid bath, and, in the case of those produced from amido-azo monosulphonic acids, to absolutely withstand fulling.—T. A. L.

*Manufacture of a New Amidonaphtholdisulphonic Acid.* C. D. Abel, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 2984, February 10, 1893.

THIS acid, which is described as a disulphonic acid of 1.8-amidonaphthol, is produced from the  $\alpha$ -naphthylamine disulphonic acid of Ger. Pat. 40,571 by conversion into  $\alpha$ -naphthylamine trisulphonic acid and subsequent removal of one sulphonic acid group by fusion with caustic alkalis. One kilo. of the sodium salt of  $\alpha$ -naphthylamine disulphonic

acid is heated on the water-bath with 3 kilos. of fuming sulphuric acid (containing 23 per cent. of  $SO_3$ ) until a sample diluted with water and treated with nitrite no longer gives a colour with phenols. The melt is then poured into water and converted into the lime or sodium salt. The neutral and acid sodium salts of the  $\alpha$ -naphthylamine trisulphonic acid, as well as the free acid, are very easily soluble in water, and the alkaline solutions have a fine yellowish-green fluorescence. In order to carry out the fusion, 1 kilo. of the sodium salt is fused with about 3 kilos. of caustic potash and some water in an open or closed vessel at 170°—220° C. until a sample diluted with water no longer shows the characteristic fluorescence of the  $\alpha$ -naphthylamine trisulphonic acid. The melt is then dissolved in water and hydrochloric acid, and the acid sodium salt of the new amidonaphthol disulphonic acid precipitates from the solution on cooling. The new acid is readily soluble in hot or cold water, yields no diazo compound, and gives a dark green solution with ferric chloride. It combines with diazo or tetrazo compounds to form valuable dyestuffs, and differs from the isomeric acid of Eng. Pat. 13,443 of 1890 (this Journal, 1891, 760) in only combining with one molecule of a diazo compound.—T. A. L.

*Improvements in the Manufacture of Unsymmetrical Diamido Bases, and of Colouring Matters therefrom.* J. C. L. Durand, E. Huguenin, and A. J. J. d'Andiran, Basle, Switzerland. Eng. Pat. 20,301, October 27, 1893.

THIS is an extension of Eng. Pat. 12,704 of 1893 (this Journal, 1893, 824), and describes the formation of a condensation product by heating together formaldehyde, tolidine, or dianisidine, and the basic hydrochloride of *m*- or *p*-phenylene diamine. If dianisidine and *m*-phenylene diamine be employed, the resulting compound has the formula—

The process is carried out in a similar manner to that already described, and the base when separated is slightly soluble in hot alcohol and benzene, but insoluble in ether. The hydrochloride and sulphate are readily soluble in water. The nitrite required for diazotising it corresponds to two amido groups, and the method for employing it in the production of colouring matters is similar to that described in the first-named patent. The condensation product now described gives a greenish-blue cotton colouring matter with  $\alpha$ -naphthol-*p*-sulphonic acid, whereas the condensation products described in the earlier specifications gave reddish-blue dyes with this component.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Action of Nitric and Nitrous Acids on Silk.* L. Vignon and P. Lislely. Romen's Journal, 1893, 5.

WHEN silk is immersed in nitric acid of sp. gr. 1.133 at 45° for one minute it becomes coloured yellow, and the colour is fast to light and air. Nitric acid when pure does not produce this effect, but only after the addition of some nitrite. The coloured silk takes up base from alkaline solutions and the colour becomes darker. A fugitive yellow is produced by an acidified solution of nitrite, but is rendered fast by the addition of nitric acid. The yellow colour is bleached by a strong acid solution of "tin salt."—A. K. M.

*The Manufacture of India-rubber Waterproof Cloth.*  
C. O. Weber. *Zeits. ang. Chem.* 1893 [21], 22.

Very little reliable information on this important branch of the india-rubber industry is to be obtained from the various books published on this subject. This is largely due to the fact that india-rubber manufacturers maintain the strictest secrecy with regard to the materials, machines, and working methods employed. It is very doubtful whether all the waterproof manufacturers combined could point out a single secret worthy of the name. On questions regarding the nature and chemical capabilities of india-rubber, which certainly will play an important part in the future development of this industry, the manufacturers are woefully ignorant.

Of the raw materials employed in this industry, india-rubber is of course the most important, Pará rubber being used almost exclusively. Of late years "recovered rubber" is used in considerable quantities along with fresh rubber. This recovered rubber is obtained by boiling cuttings from waterproof cloth with dilute hydrochloric acid, whereby the cloth is destroyed, thin films of "proofing" remaining behind, which are then washed and subsequently dried. India-rubber substitutes, obtained by treating colza oil with sulphur monochloride, or by boiling castor oil with sulphur, are also largely employed. Free oil and free fatty acids, which these substitutes may contain if not carefully prepared, are apt to act upon the india-rubber most injuriously. The mineral substances added for weighting or colouring the proofing are safe if they are insoluble in water and do not contain any oxides capable of acting as oxygen carriers. As solvents for the india-rubber, petroleum benzine and a mixture of toluene, xylene, and cumene are almost exclusively used. Neither of these solvents should contain any fractions boiling above 140° C. The vulcanising agents are sulphur and sulphur monochloride. Fawcitt's antimony iodide has not been much used so far; its practical advantages seem as doubtful yet, as its vulcanising action appears mysterious. Adulteration of sulphur is practically an unknown thing; if suspected, its solubility in carbon bisulphide readily affords the desired information. Sulphur monochloride may contain large quantities of free sulphur and also sulphur bichloride. Both these impurities are liable to cause trouble in the vulcanising process. Sulphur monochloride should therefore always be analysed before use. This is done by determining its percentage of chlorine, of which the monochloride contains 52.6, the bichloride 68.9 per cent., so that the presence of 3 per cent. of bichloride in a sample of monochloride can be easily detected, and this quantity is considered unobjectionable. The analysis is carried out by filling a small glass stoppered bottle with the monochloride and weighing it. From 20 to 30 grms. of this monochloride are then poured off into a 1,000 cc. flask containing about 500 cc. of water, and decomposition is effected by shaking the bottle vigorously for some minutes. The weight of the decomposed monochloride is found by subsequently weighing the small bottle. The monochloride being decomposed, the flask is warmed on the water-bath, and for every gram. of decomposed monochloride 1 cc. of nitric acid (1.42) is added, the flask well shaken, cooled, and then filled up to the mark with water. In the solution so obtained the chlorine is then determined gravimetrically or volumetrically. The following analyses were made in this manner:—

I. Used 22.88 grms. of  $S_2Cl_2$ : carefully purified specimen.

After decomposition oxidised with 23 cc. of  $HNO_3$ .  
50 cc. of filtrate yield 2.428 grms.  $AgCl = 0.601$  grms.  $Cl$ .

Total  $Cl = 0.601 \times 20 = 12.02$  grms. = 52.53 per cent. (calcn. 52.6).

The sample contains 99.86 per cent. of  $S_2Cl_2$ .

II. Used 24.39 grms. of  $S_2Cl_2$ . Reddish amber-coloured liquid.

After decomposition oxidised with 24 cc. of  $HNO_3$ .  
50 cc. of filtrate yield 2.224 grms.  $AgCl = 0.550$  grms.  $Cl$ .

Total  $Cl = 11.00$  grms. = 45.10 per cent.

The sample therefore contains  $\begin{cases} 85.9 \text{ per cent. } S_2Cl_2 \\ 11.1 \text{ per cent. } S. \end{cases}$

III. Used 20.74 grms. of  $S_2Cl_2$ . Colour dark red-orange.

After decomposition oxidised with 21 cc. of  $HNO_3$ .  
50 cc. of filtrate yield 2.27 grms.  $AgCl = 0.502$  grms.  $Cl$ .

Total  $Cl = 11.24$  grms. = 54.1 per cent.

The sample therefore contains  $\begin{cases} 89.57 \text{ per cent. } S_2Cl_2 \\ 10.41 \text{ per cent. } SCl \end{cases}$

In connection with chloride of sulphur, carbon bisulphide must be mentioned, which should be as pure as possible. It contains generally some free sulphur, but seldom in objectionable quantities. The more or less nauseous smell of the commercial bisulphide seems to be due to two different substances, the composition of which is not known. The iron drums in which the bisulphide is stored frequently contain water, which must be carefully kept out of the vessels in which the bisulphide is mixed with the chloride of sulphur. The safest plan is to keep the bisulphide in storage tanks containing a quantity of burnt lime, as in this manner the bisulphide is always perfectly dry, and at the same time most of the objectionable impurities are retained by the lime. Amongst the raw materials for the waterproofing industry, also the textile fabrics must be classed, as they occasionally contain impurities which cause the deterioration of the india-rubber coating upon these fabrics. Best known in this respect are oils and free fatty acids in cloth, and as a rule cloth containing more than 2 per cent. of either of them is considered dangerous. Much more objectionable, however, is the presence of copper and manganese compounds in a cloth, exceedingly small quantities of which show a most destructive effect upon the india-rubber coatings. It is remarkable that of the numerous colouring matters, Bismarck brown is the only one which is detrimental to india-rubber.

The compounds mixed with the india-rubber in the preparation of the india-rubber "dough" are exceedingly varied, but no chemical considerations of any kind enter into their selection. The textile fabrics, after having received a sufficient number of coatings, are vulcanised either by the cold or by the hot process. In the first case the vulcanising agent employed is a solution of sulphur monochloride in carbon bisulphide. The concentration of this solution is generally stated much too high; it is used containing from 0.5 to 3 per cent. of sulphur monochloride. Equally unreliable are the statements regarding the amount of sulphur taken up by the india-rubber, and the temperature required in the hot vulcanising processes. It is, however, certain that the quantity of sulphur added to the india-rubber is always in excess of the quantity entering into combination with it. The vulcanising temperature is occasionally given as low as 210° F. This is obviously erroneous, being considerably below the melting point of sulphur. The vulcanising temperature should therefore not be less than 235° F., and it is certainly preferable to vulcanise at a higher temperature than this. The higher the temperature employed the shorter is the time required for vulcanisation. Using 6 per cent. of sulphur at 260° F., the vulcanisation is complete in two hours.—C. O. W.

## PATENTS.

*Improvements in the Manufacture of Linoleum, Kamptulicon, and other similar Floor Cloths, and in the Means employed in such Manufacture.* J. S. Farmer, Salford, and H. L. Storey and L. H. Storey, Lancaster. Eng. Pat. 23,983, December 29, 1892.

A ROLLER is prepared containing grooves corresponding to the fine lines and narrow spaces in a pattern or design. The grooves are filled with the material of which the floor-cloth is made, and the contents of the grooves are discharged on to the foundation fabric of the cloth. The solid colour blocks are then placed in their proper positions, and by means of pressure the material discharged from the grooves is squeezed and caused to fill up the interstices between the solid colour pieces.—R. B. B.

*Improvements in the Treatment of Cotton Cloths for Filtering Purposes.* H. E. Newton, London. From E. de Haen, List vor Hanover, Germany. Eng. Pat. 1770, January 26, 1893.

THE cotton cloths used for filtering acid liquids in filter presses are rapidly destroyed. Wool is too expensive to be commonly employed for this purpose. Nitrated cellulose withstands the action of acids much better than cotton, but the ordinary methods of nitration do not yield a suitable product. The patentee proposes to modify the nitrating process thus:—The cotton is immersed in cold nitric acid at 40°–50° B. for one hour, then steeped in cold sulphuric acid 62°–68° B. for one hour, and well washed. The material thus prepared withstands the action of all acids, and is even more durable than the woollen material sometimes employed for filtering purposes.—R. B. B.

*Improvements in the Method of and Apparatus for Washing Wool and other Fibres.* P. Kelly, Cross Hills, Yorks. Eng. Pat. 1897, January 28, 1893.

THE water or other washing liquid is stored in tanks, and drawn off as required into a cistern, which contains within it a smaller cistern. This inner vessel has perforated sides and bottom, and there is a clear space all round the sides and underneath it. The material is placed in the smaller cistern, and the liquid allowed to flow from the storage tank into the space between the two cisterns, whence it flows through the perforations and saturates the fibre. Within the smaller cistern a plate is caused to alternately rise and fall. On falling it presses on the fibre, squeezing the liquid from it, and on the motion being reversed the pressure is released, and the liquid flows again through the perforations and saturates the fibre. The reciprocating motion of the plate is continued until the washing is complete.

—R. B. B.

*Improvements relating to the Treatment of Fabrics and other Stuffs for the Purpose of Obtaining a Substitute for Ornamented Leather, Tapestry, Brocade, Embroidery, and the Like.* H. B. Lake, London. From the Fratelli Mora, Milan, Italy. Eng. Pat. 16,989, September 9, 1893.

THE materials employed are steeped in water, dried, and then coated with some preparation of a farinaceous, gummy or oleaginous nature. This coating may consist of starch, gum arabic, fish glue, boiled oil, or other substance, either alone or mixed with sawdust, bran, &c. The coating is applied by hand or by immersing the fabric in a bath containing the necessary ingredients. After drying the material is "satined" if a polished surface is required. It may then be embossed by engraved rollers or with hand stamps, and finally is coloured, bronzed, gilded, &c., as required.

—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

*Some Properties of Lead Oxides.* A. Bonnet. Comptes rend. 1893, 117, 518–519.

WHEN cotton is mordanted in an alkaline plumbate, and well washed, the fibre becomes charged with the pure oxide of lead. The oxidising power of this body causes the destruction, more or less, of the fibre. A similar dissociation takes place when plumbites are used, without the inconvenience of oxidation, and the white oxide plays a part in a series of other reactions. Mordanted cotton immersed in baths of logwood, sumac, &c., immediately forms, especially with heat, a coloured lake, black with logwood, yellow-green with sumac. It is also possible with this mordant to deposit on a fabric most of the metallic

oxides by employing suitable baths. Gold, silver, mercury, vanadium, manganese, chromium, iron, cobalt, nickel, and zinc give characteristic reactions if solutions of neutral salts be used. These reactions are so marked that, for example, it is sufficient to use a bath of permanganate of potash containing 0.25 grm. of the salt per litre, to obtain at 80° or 90° a very dark deposit of binoxide of manganese. Traces of vanadium in an ammoniacal chloride solution are at once detected.

This displacement of the oxides is explained by the formation of salts of lead soluble by heating. In the same manner the chlorides of iron, cobalt, nickel, and chromium decompose with heat, depositing upon the material the corresponding oxide; at the same time a chloride of lead is formed in the bath which is soluble with heat, but is precipitated on cooling.—D. E. J.

*Indigo Salt, a New Preparation for the Dyeing of Indigo on Cotton.* E. Fischer. Chem. Zeit. 1893, 17, 1069.

THE indigo blue thus produced is stated to be brighter and much faster to soap and rubbing than ordinary indigo prints. Its use for discharge styles also possesses material advantages over the ordinary indigo. (This Journal, 1893, 908 and 988).—C. O. W.

## PATENTS.

*Process for Bleaching Raw Starch, Starch Gum, and Solutions thereof by Treatment with Chlorine and Ozone combined.* Siemens, Bros., and Co., London. From Siemens and Halske, Berlin, Germany. Eng. Pat. 2597, February 6, 1893.

THE raw starch is made into an emulsion with water, and subjected to the action of currents of chlorine and ozone, either simultaneously, or the treatment with chlorine may precede that with ozone. The bleached starch may then be converted into starch gum by well-known processes.

Or the gum may be first produced from starch and then bleached in a similar manner.

The chlorine may be employed in aqueous solution instead of in the gaseous state.—R. B. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Synthetic Formation of Citric Acid by Fermentation of Glucose.* C. Wehmer. Comptes rend, 117, 332.

See under XX., page 57.

*Action of Certain Metals on Acid Solutions of their Chlorides.* A. Ditte and R. Metzner. Comptes rend, 1893, 117, 691.

See under XI., page 43.

*The Production of various Carbides.* O. Mühlhäuser. Dingl. polyt. J. 1893, 289, 164–168.

FIFTEEN elements are known to form carbides. Of these the following are metallic: K, Ca, Ba, Fe, Mn, Cr, U; while the non-metallic are H, Cl, Br, I, O, S, N, B, Si.

The most noteworthy of the metallic carbides are the under-mentioned:—

*Potassium carbide*,  $K_2C_2$ , is prepared by passing acetylene over fused potassium. It is also found as a by-product in the manufacture of potassium.

*Calcium carbide*,  $CaC_2$ , is formed by heating a mixture of calcium, zinc, and carbon to a white heat, or by heating calcium carbonate with magnesium and carbon. Barium

carbide is prepared in a manner analogous to that by which the calcium compound is prepared. All these carbides have the property of evolving acetylene when treated with water.

*Iron carbide* has not hitherto been allotted a definite formula, as the amount of carbon which iron is capable of taking up depends on various conditions. The maximum amount may be taken as 4.6 per cent. of carbon. It is worthy of remark that the substance used by Castner in the preparation of sodium appears to be an iron carbide.

*Manganese carbide* has been investigated by Wahl and Green and by Moissan. The former ascribe to it the formula  $Mn_3C$ , while the latter has prepared bodies with a content of carbon ranging from 6.3 to 14.6 per cent. by means of the electric furnace.

*Chromium carbide*, containing carbon varying from 8.6 to 11.9 per cent. of C, has been prepared by Moissan by the same means.

*Uranium carbide* with 5 to 13 per cent. of C has also been obtained by the same investigator.

Carbides of the non-metallic elements which claim comment are—

*Sulphur carbide* (carbon disulphide) which can be obtained in a manner different from that in which it is manufactured, viz., by heating a mixture of calcium sulphate and carbon in the electric furnace. The following reaction is said to occur:— $2CaSO_4 + 13C = 2CaC_2 + CS_2 + 8CO$ .

*Boron carbide* is obtained by heating a mixture of boric anhydride with excess of carbon in an electric furnace. The progress of the reaction is distinguished by the following stages. The mass softens and decomposition sets in with the evolution of carbon monoxide, which causes the formation of bubbles in the charge until the whole of the boron is converted into carbide. On cooling, the boron carbide is found in rounded masses of metallic lustre, embedded in the excess of carbon. In order to separate it from its matrix, the whole product is powdered and heated to dull redness in a stream of oxygen by which means the whole of the free carbon and a part of that combined with the boron, are oxidised. The residue is powdered and treated successively with caustic soda, water and hydrochloric acid. A powder having the appearance of graphite, and like that substance possessing the property of staining the fingers, is obtained. On heating, the boron carbide becomes spongy and plastic, and on further heating, fuses. It can only with difficulty be burnt in oxygen, but is readily oxidised by lead chromate. It has the composition indicated by the formula  $BC$ . On fusion with sodium carbonate it yields sodium borate and carbon dioxide.

*Silicon carbide* is produced when a mixture of sand, carbon, and common salt is heated in the electric furnace. The charge, consisting of equal parts of sand and carbon with a little salt, is introduced into the furnace and connection between the electrodes made by a layer of powdered carbon, the whole being then covered with a further quantity of the mixture. During the reaction, evolution of gas takes place, and on its cessation the reduction may be considered complete. On examining the contents of the furnace it is found that the carbon core which serves to connect one electrode with the other, has suffered no change, but that there is a zone immediately surrounding the path of the current consisting of a shining black crystalline mass disposed radially, containing about 66 per cent. of free carbon and 33 per cent. of silicon carbide. The free carbon is distinctly graphitic, staining the fingers, &c. The composition of the silicon carbide separated from this matrix is as follows:—Silicon, 68.26; carbon, 30.49; ferric oxide, 0.77; lime, 0.48 per cent.

In order to separate silicon carbide from admixed graphite, it is heated to redness in a stream of oxygen. The properties of the substance obtained in this zone of the reaction are almost identical with those of that formed in the zone immediately exterior to it, the only difference consisting in small variations in optical behaviour. The main product of the reaction occurs, as already stated, immediately exterior to the zone of mixed carbide and free carbon. The crystals, which have a greenish tinge, are disposed radially to the

electrodes of the furnace. A sample analysed had the following composition:—Silicon, 62.70; carbon, 36.26; ferric oxide and alumina, 0.93; magnesia, 0.11 per cent.

The purification of the carbide is effected by successive treatment with hydrochloric acid, dilute caustic soda and water. The dried powder is heated to dull redness in a stream of oxygen for an hour, and the product treated with hydrofluoric acid together with a little sulphuric acid, whereby it is obtained approximately pure. The substance thus purified has the composition:—Silicon, 69.10; carbon, 30.20; ferric oxide and alumina, 0.46; lime, 0.15 per cent.; and corresponds fairly well with the formula  $CSi$  which requires 70 per cent. of silicon and 30 per cent. of carbon. When pure carbon and silica are used, colourless crystals are obtained, but with the usual materials enough iron is present to give the crystals a greenish or greenish-yellow colour. Silicon carbide is not sensibly soluble in any acid, nor is it appreciably attacked by dilute solutions of the alkalis but is decomposed by fusion with sodium carbonate or caustic soda, sodium silicate being formed and the carbon set free in a condition in which it eventually takes fire, leaving the melt white. Silicon carbide has the curious property of remaining suspended in water for months when finely powdered, but it is precipitated by the addition of an acid or a salt. The zone exterior to that containing the crystals of silicon carbide, consists of a mass of particles of the same size as the original grains of sand. These particles have a similar composition to the silicon carbide already described, and can be purified in the same way but are much softer and can be readily powdered. An analysis of this variety is as follows:—Silicon, 65.42; carbon, 27.93; ferric oxide and alumina, 5.09; lime, 0.38; magnesia, 0.21 per cent.

It appears to be identical with a substance prepared by Schützenberger and is the amorphous variety of silicon carbide formed at a lower temperature than that which is crystalline.

Crystalline silicon carbide is now an article of commerce under the name "Carborundum," and seeing that in hardness it is but little inferior to the diamond it is not surprising that it has been already adopted for grinding and polishing purposes.—B. B.

*Hyponitrous acid.* A. Thum. Monatsh. Chem. 1893, 14, 294.

HYPONITROUS acid  $H_2N_2O_2$  is obtained by the reduction of nitrite of soda by sodium or ferrous hydrate. The reaction proceeds in the following manner:—

I.

II.

III.

Excess of the reducing agent should be avoided, as it proves detrimental to the yield of hyponitrous acid. If instead of sodium, ferrous hydrate be employed as the reducing agent, also smaller yields are obtained. Anhydrous hyponitrous acid cannot be obtained by decomposing dry hyponitrite of silver by means of sulphuretted hydrogen owing to the liability of this acid to explode spontaneously even at very low temperatures. Solutions of the acid are, however, easily obtained by decomposing the silver salt by means of hydrochloric acid. This solution possesses a very acid reaction and is not altered by boiling with dilute acids or alkalis. Permanganate of potash in the presence of sulphuric acid oxidises the solution quantitatively into nitric acid, whilst in alkaline solution the oxidation only proceeds as far as conversion into nitrite. Nitrous acid completely decomposes hyponitrous acid. Hyponitrous acid is a dibasic acid, as is proved by the existence of an acid barium hyponitrite. It liberates no iodine from an

acid solution of potassium iodide, nor does it prevent such a liberation by the action of nitrous acid. Hyponitrous acid is very indifferent to reducing agents and is not affected by boiling with dilute sulphuric acid and zinc. Reducing agents in alkaline solutions slowly destroy it.—C. O. W.

*New Processes and Apparatus for Concentrating Sulphuric Acid.* M. M. Gerber. *Monit. Scient.* **41**, 366—369.

This paper completes the description given in September 1892 (*see also* this Journal, 1892, 434), of Kessler's process. The process depends upon the action of heated air or gases, passed over or through the acid, whereby the concentration is effected at a temperature considerably below that of the boiling point *in vacuo*. Thus, while concentrated sulphuric acid boils under ordinary pressure at 328° C., and *in vacuo* at about 230°, the chamber acid is concentrated up to 66° B. in Kessler's apparatus at a temperature not exceeding 170° C., and leaves the apparatus at 120°, flowing into a receptacle wherein it gives up its heat to the chamber acid intended for concentration. The effluent gases also escape at a temperature so low as to occasion very little loss of heat.

The apparatus includes a furnace in which coke is burned, the products of combustion being led into a "saturator" divided into compartments, superposed upon which is the "recuperator," with tiers of communicating vessels, containing the acid to be concentrated 2 to 4 c.m. in height, having at alternate ends overflow pipes to successive tiers, and then into the "saturator" wherein the concentration is completed. There are caps to the acid-containing vessels, so arranged that the entering heating gases bubble through the acid in their progress; the arrangement being similar to that of the distilling apparatus of Derome or Savalle. The dome-shaped head to the "recuperator" opens into a pipe, curved so as to lead horizontally to the bottom of a vessel charged with small coke, which filters the gases free from any acid vapours, these condensing, and the liquid being collected. Some slight pressure or suction is necessary to cause the heated gases to bubble up through the layers of acid, both in the "saturator" and the "recuperator," which may be obtained by the draught of a chimney, or as is shown in the drawings of the apparatus, by a steam-jet operating in the horizontal tube leading from the "recuperator" to the condenser. The rectangular trough constituting the "saturator" is formed of an acid-resisting stone, lined with resisting cement, and divided by partitions, slightly dipping into the acid, into compartments, so that the heated gases passed in by a cast-iron pipe pass from compartment to compartment by bubbling under the immersed sides. The "recuperator" may be made wholly of lead; but preferably the uppermost tier, containing the weakest acid, and not subjected to a higher temperature than 110° C., is of lead, while the lower tiers are of similar resisting material to the "saturator."

The fuel used to obtain the heated gases is small gas coke, the consumption of which does not exceed 8 to 10 kilos. per 100 kilos. of acid at 66° B. produced from chamber acid of 52 B. The gases should not enter the concentrating apparatus at so high a temperature as 500° C., as in that case, the strength of the acid obtained is under 66° B., this being accounted for by the tendency to dissociation of the monohydrated acid into the anhydride or pyro-acid and water, as the temperature approaches the boiling point of the acid. The apparatus described has been in use for the past two years in the Clermont-Ferrand works.

—E. S.

*Lead Tetrachloride.* H. Friedrich. *Monatsh. f. Chem.* **14**, 1893, 505—520.

AMMONIUM chloroplumbate,  $\text{Pb}(\text{NH}_4)_2\text{Cl}_6$  or  $2\text{NH}_4\text{Cl}, \text{PbCl}_4$ , is prepared by treating pure lead chloride,  $\text{PbCl}_2$ , with about 20 parts of strong hydrochloric acid, and saturating with chlorine at 10—15° C., whereby almost complete solution ensues, forming a dark yellow clear fluid, smelling strongly of chlorine. To this ammonium chloride is added dissolved in 10 parts of water, both fluids being previously cooled by ice. In a short time a crystalline

precipitate forms, of a yellow colour with slight greenish tinge; if too strong ammonium chloride solution were used, this is apt to contain particles of salammoniac; but if not, it is practically pure ammonium chloroplumbate, furnishing sharp numbers on analysis after collection on a pump-filter, and washing with icecold alcohol which has no action on it. About two-thirds of the theoretical yield are thus obtained.

By dropping this double salt little by little into concentrated sulphuric acid cooled with ice, an oily yellow liquid is ultimately obtained, consisting of lead tetrachloride,  $\text{PbCl}_4$ . The first action gives rise to hydrochloric acid and particles of solid ammonium sulphate, which forms a sort of milky fluid with the sulphuric acid; when the oil has sufficiently accumulated the acid is poured off, and the oil agitated with fresh acid until clear and free from suspended solid matter. Lead tetrachloride thus obtained is a heavy highly refractive fluid resembling antimony pentachloride; it fumes in the air like tin tetrachloride, emitting an odour resembling that of hypochlorous acid, and causing a sweet taste to be perceptible in the mouth. It can be preserved under sulphuric acid, but is liable to explode, especially when heated to 105°, lead chloride,  $\text{PbCl}_2$ , and free chlorine being formed. Two determinations of its specific gravity at 0° gave the values 3.182 and 3.184, mean 3.183. In a freezing mixture it solidifies to a transparent yellowish crystalline mass, which melts at about -15° C. It forms a crystalline compound with hydrochloric acid, probably  $\text{H}_2\text{PbCl}_6$ , when in contact with a small quantity of cooled concentrated acid; larger quantities dissolve it in all proportions, forming solutions from which salammoniac precipitates ammonium chloroplumbate. Contact with large quantities of water forms lead dioxide and hydrochloric acid, a similar result being observed with ammonium chloroplumbate. By cautiously passing a current of dry chlorine through a retort containing sulphuric acid in which lead tetrachloride is suspended, the whole being gently heated, a small amount of volatilised substance can be condensed in a chilled receiver, showing that the compound is volatile. In all these general properties a very close resemblance is noticeable between tin tetrachloride and lead tetrachloride; more especially in that both of these compounds resist the action of sulphuric acid, whilst both tin dichloride and lead dichloride are readily acted on with evolution of hydrochloric acid. Germanium tetrachloride is also unattacked by concentrated sulphuric acid, even on warming; on the other hand antimony trichloride and pentachloride are both decomposed with evolution of hydrochloric acid, as also are both ferrous and ferric chlorides in the anhydrous condition.

Attempts to prepare lead tetrabromide, and the alkaline bromoplumbates proved unsuccessful: on cooling in ice for 10—12 hours a mixture of lead bromide and potassium bromide solution containing free bromine, a reddish brown crystalline body separated; this immediately decomposed on removal from the liquid with evolution of bromine, leaving a white residue containing lead bromide and potassium bromide; whence its composition presumably was that of potassium bromoplumbate,  $\text{K}_2\text{PbBr}_6$ .—C. R. A. W.

*The Specific Gravities of Solutions of Bleaching Powder.* G. Lange and F. Bachofen. *Zeits. angew. Chem.* 1893, 326—328.

This investigation was carried out for the purpose of establishing the relationship existing between the specific gravities of bleach solutions and the available chlorine contained therein. The difficulties attending this research may be reduced to the difficulty of obtaining a fairly representative sample of bleaching powder, since, as is well known, "bleach" gradually loses its available chlorine, and calcium chloride and calcium chlorate are formed as secondary products. The authors base their results on what they consider a fair average sample of well-made bleaching powder, such as is found in the market, and consider that this very fact will enhance the value of their investigation.

In the first instance, a concentrated solution of bleaching powder was prepared and kept protected from air and light.

It was analysed, its specific gravity taken, and other solutions prepared therefrom by suitable dilution. At the conclusion of the investigation, which was carried out with the utmost expedition, the original liquor was tested over again and found to be practically unchanged. The available chlorine was estimated according to Penot's method and the results so obtained checked by the hydrogen peroxide method (this Journal, 1890, 21—24). The results thus obtained being a trifle too high were discarded in favour of those yielded by Penot's method. The chlorine present as calcium chloride was estimated after adding the exact quantity of arsenious acid required by the former test, then acidifying with nitric acid and titrating with silver nitrate, by deducting from the chlorine thus obtained, the quantity of available chlorine as determined by the arsenious acid test. Another sample served for the determination of the chlorate by means of ferrous sulphate and permanganate, deducting from the result the quantity of hypochlorite. The liquor contained:—

	Grms. per Litre.
Available chlorine .....	72.17
Chlorine as chloride .....	6.74
Chlorine as chlorate .....	0.13
Lime .....	65.53

or calculated on the corresponding salts:—

	Grms. per Litre.
CaOCl <sub>2</sub> .....	129.09
CaCl <sub>2</sub> .....	10.54
Ca(ClO <sub>3</sub> ) <sub>2</sub> .....	0.38
Ca(OH) <sub>2</sub> .....	4.21

The specific gravities were taken at 15° C. by means of officially certified hydrometers (a series of 21, ranging from sp. gr. 0.76—2.0), which could be read to 0.0005. The readings were found to be in perfect agreement with pycnometer determinations. The solutions were approximately diluted to the required strength, cooled to somewhat below 15° C., then allowed to stand until the temperature rose just to 15° C., and diluted with water to the proper specific gravities. The results marked by an asterisk are obtained by interpolation. When plotting the results, a slightly convex line is obtained. The uncorrected experimental data are found in column B., whilst in column C. allowance is made for the very slight irregularities of the curve. The values of any specific gravities not here given may be calculated with perfect accuracy by interpolation.

*The Action of Ammonia Gas on Peroxides.* O. Michel and E. Grandmougin. *Ber.* 26, 1893, 2565—2568.

The authors adopted the following method of investigation. The peroxide under examination, contained in a porcelain boat, was heated in an ordinary combustion-tube placed in a gas furnace. Dry ammonia gas was passed through the tube and the permanent gases given off collected over sulphuric acid and analysed.

The following observations were made:

*Sodium peroxide.*—The oxide at first turns yellowish and a small quantity of oxygen is given off. It then fuses, becomes brown, and froths up, giving off at the same time large volumes of practically pure nitrogen. After a time the evolution of gas ceases, the mass sets and again becomes white. The residue in the boat was found to have the following composition:—NaHO, 91 per cent.; NaNO<sub>2</sub>, 6 per cent.; NaNO<sub>3</sub>, 3 per cent. The main reaction evidently, therefore, proceeds according to the equation—

*Barium peroxide.*—In this case the reaction requires a higher temperature. The oxide fuses and pure nitrogen is formed. The residue consists of barium hydrate, no trace of nitrate or nitrite being produced.

*Manganese peroxide.*—The oxide is reduced to MnO, and nitrogen and water are formed. At high temperatures, however, further reduction occurs and nitrous fumes are formed.

*Lead peroxide* turns yellow and is reduced to PbO with violent evolution of gas and water vapour. At the same time ammonium nitrate and nitrite and nitrous fumes are produced.—H. T. P.

#### PATENTS.

*Improvements in the Preparation of Chromic Acid, and in the Extraction of Pure Acids from Alkaline Salts.* E. Placet and J. Bonnet, Paris. Eng. Pat. 22,819, December 12, 1892.

Pure chromic acid is obtained by electrolysis of an alkaline chromate or bichromate, the chromate solution being placed in a vessel within which is a porous vase, the latter being charged with water or the same solution. Electrodes of carbon, or other unattackable conducting body, are used, the positive pole of the source of electricity being connected to the carbon in the main body of the solution, and the negative pole to the carbon within the porous vase. The chromate solution is fed with the salt as required, and the alkaline solution found in the vase is removed from time to time and replaced by the original liquid. The chromic acid separated in the outer vessel is crystallised in the ordinary manner. The separated alkali may be utilised for treating chrome minerals; or in obtaining alkali chromates. A number of applications are specified for the chromic acid, and in this connection reference is made to three patents, Nos. 22,854, 22,855, and 22,856 of 1891.

The process is stated to be applicable generally to the extraction of pure acids from binary compounds.—E. S.

*Improvements in the Manufacture of Cyanides and Cyanogen Compounds.* J. D. Gilmour, Glasgow, Eng. Pat. 24,116, December 31, 1892.

A mixture of carbon, alkali, alkaline oxide or carbonate, or alkaline earth, (but preferably potash), is strongly heated in a current of nitrogen obtained in a subsequent stage of the process. The product, more or less converted into cyanide, is lixiviated, and carbonic acid gas is passed through the solution, which is preferably at boiling heat. The hydrocyanic acid that is disengaged, is condensed and added to strong sodium hydroxide solution to obtain sodium cyanide. The carbonic acid required is obtained by burning carbon in air to obtain a mixture of carbonic acid and nitrogen, which mixture, when led through the solution, where the CO<sub>2</sub> is

absorbed in liberating HCN, leaves nitrogen after condensation of the hydrocyanic acid, which is utilised, as first described, in assisting in the formation of a cyanide.

—E. S.

*Improvements in Apparatus for the Making or Manufacture of Caustic Soda or Caustic Potash, being a Method of Passing the Chlorine and Sodium Gases to the Receiver.* F. W. Petrie, Rochdale. Eng. Pat. 472, January 10, 1893.

THE invention consists in improvements upon Eng. Pat. 15,792, 1889, and especially upon Eng. Pat. 12,977, 1892, relating to the electrolytic production of caustic soda or caustic potash. The object of the present improvements is to remove the gases (chlorine and sodium vapour) from the electrolytic generating chamber, the chlorine by means of a blower or fan connected to a tube entering one compartment of the chamber; and the sodium vapour by a fan intercepting between the chamber and the receiver. The chlorine is conducted to a chamber containing lime, for production of bleaching powder. The receiver for the sodium is called the "caustic soda chamber." A vertical tube communicating with the atmosphere is shown entering the sodium compartment of the electrolytic apparatus, whereby, as the fan rotates, "an admixture of air with the metals is obtained," "facilitating the conversion of the sodium metal into a gas," besides "withdrawing the same from the generating chamber."—E. S.

*Improvements in the Treatment of Manganates for the Production of Permanganates suitable for use for Disinfecting or other Purposes, and in Apparatus therefor.* W. J. Menzies, Malpas, Chester. Eng. Pat. 1213, January 19, 1893.

ALTHOUGH permanganates are excellent disinfectants, their high price forbids their general use. On the other hand, the cheaper manganate of soda must be used in conjunction with sulphuric acid, and this constitutes a serious disadvantage. Another objectionable feature is that the commercial article contains much caustic soda. The object of this invention is to convert manganate of soda into permanganate by means of carbonic acid. The simplest way of doing this is to mix the salt intimately with 1 to 1½ times its weight of bicarbonate of soda; or the conversion may be effected by carbonic acid gas.—H. T. P.

*Improvements in and Apparatus for the Manufacture of Bleaching Powder.* E. K. Muspratt, Liverpool, A. Carey, Browside Gateacre, Lancaster, and V. C. Driffield, Lancaster. Eng. Pat. 1214, January 19, 1893.

IN treating lime with dilute chlorine in compartmented apparatus, excessive heating is prevented by causing the gas to pass from compartment to compartment through tubes which may be connected to cooling coils immersed in water or otherwise. Or, the communicating pipe may be of such length that the heat of the gas may be dispersed. The intermediate cooling apparatus may be modified in described ways, to suit requirements.—E. S.

*Improvements in the Extraction of Carbonic Acid from Mineral Carbonates, and in Apparatus therefor.* A. Van Berkel, Berlin. Eng. Pat. 2274, February 1, 1893.

THE mineral carbonates are strongly heated in a rotating drum set in a suitable heating chamber, on trunnions, one of which is hollow, the opening to the interior of the drum being guarded by a perforated cap. The pipe from the hollow trunnion communicates with a suction pump, by which the gas is drawn off as it forms. The sides of the drum are corrugated or provided with deep hollows, so that as it rotates, the mineral is carried upwards till it falls through the heated space within the drum, and so continuously. The drum is provided with a suitable manhole for charging and discharging.—E. S.

*Improvements in the Manufacture and Production of Salts or Compounds of Alumina or Aluminium.* J. L. Kessler, Clermont-Ferrand, France. Eng. Pat. 2710, February 7, 1893.

THE invention mainly consists in freeing aluminium sulphate from iron by causing it to crystallise with sodium sulphate to form soda alum, the iron being then left in the mother-liquor. As a preliminary treatment, it is preferred to boil the solution of the aluminium salt with a soluble phosphate, or with calcium or aluminium phosphate in small proportion. When the alumina precipitated is white, the quantity of calcium phosphate added is known to be sufficient.

Reference is made to Augé's process for obtaining soda alum, described in the French Patent No. 201,440, and its differences from the present processes are pointed out. The inventor has discovered that a solution of soda alum is liable, under certain conditions, to yield a cheesy magma of minute crystals, which crystals contain less water than the true sodium alum crystals, which latter are larger and transparent. And a crystallisation of either kind may be induced in liquors at certain temperatures or of certain densities, by introducing crystals of the true alum, or a portion of the magma. A number of processes are described in detail, whereby the desired kind of crystals may be obtained. According to one of these processes, a magma as obtained in Augé's process, is in the moist state set to drain with addition of the true alum crystals, when the mass becomes transformed throughout, without stirring, into the desired form of crystals. Also, if the solution of the alum is evaporated until it attains a temperature of 107° to 110° C. In another process, the soda alum is formed at a low temperature by alternate additions of aluminium sulphate and of sodium sulphate. Or a boiling solution of aluminium sulphate at 52° B. is allowed to cool to 90° C., and a cold mother-liquor from a preceding operation is added, or a cold saturated solution of soda alum, sufficient to lower the temperature to 40° C., and having a density of 40° B., and then the required proportion of sodium sulphate crystals are added to form the alum. The cold produced by the solution of the sodium sulphate crystals, causes the "zone of dangerous temperature" at which the objectionable magma is formed, to be passed, and on cooling, the true alum crystals are deposited. These may serve as examples.

Purification of the crystals obtained is effected by continuous washing by processes of displacement or clarification, as used in lixiviating crude soda.

In preparing aluminium sulphate for making soda alum, it is preferred to act on the aluminous matter by sodium bisulphate and excess of sulphuric acid. Details are given.

Soda alum is partly dehydrated and obtained as a translucent porcelain-like salt, by concentrating its solution by means of thick lead steam coil until the temperature rises to 115° C., when it is run out to set.

A salt "enriched with aluminium" is prepared by cooling the soda alum solution to below 10° C., the solution being sufficiently diluted to retain aluminium sulphate, whilst crystals of sodium sulphate separate. The enriched salt "being drained is evaporated in the manner and in the forms customary for sulphate of alumina." It may be rendered basic by addition of alumina.—E. S.

*An Improved Method of Producing Ammonium Formate, and from this Hydrocyanic Acid.* P. R. de Lambilly, Nantes, France. Eng. Pat. 3735, February 20, 1893.

CARBON monoxide is saturated with ammonia and the mixture passed through tubes heated to 100°—130° C. and containing porous substances capable of occluding gases, such as punice or animal charcoal, and either platinised or not. Ammonium formate in the form of vapour is thus produced, and may be condensed and collected if desired, or it may be utilised for the production of hydrocyanic acid by passing the vapours direct through a second set of tubes heated to a temperature of at least 210° C. and also containing some porous material. At this temperature ammonium formate is decomposed into water and hydrocyanic acid.—A. K. M.

## VIII.—GLASS, POTTERY, AND ENAMELS.

### PATENTS.

*Improvements in the Manufacture of Glass Articles in Imitation of Agate.* Count Solms-Baruth, Silesia. Eng. Pat. 10,384, May 26, 1893.

The glass used may have the following composition:—Basalt, 100; soda, 50; borax, 10; carbonate of lime, 20; sand, 80 parts; and chloride of silver, 1 part.

Into the molten glass are introduced pieces of basalt, lava, slag, iron ore, or burnt pyrites, after which dichloride of tin is added to the mixture. Owing to the incomplete solution of the basalt, &c., a turbidity is produced, giving an appearance similar to that of agate. By cooling the outer surface of the glass more rapidly, an improved effect is obtained by the production of a deeply-coloured surface upon a light background.—V. C.

*Improvements in or relating to Apparatus for Drying "Slip" and Evaporating Liquids.* S. Peake, Gillow Heath, near Congleton. Eng. Pat. 15,616, August 17, 1893.

The invention has reference to means for drying "slip" used in the manufacture of tiles, jet and Rockingham ware, and the like. A series of steam pipes connected together in the form of a gridiron are suspended by a chain over the "slip" kiln or other container. The pipe system is lowered into the "slip" to heat it and thereby evaporate the moisture until a sufficient degree of consistency is obtained. In order to conveniently lower the piping, swivel unions are employed at the joints; the condensed water in the steam-pipes is got rid of by means of a steam-trap attached at any suitable point.—E. G. C.

*Improvements in the Manufacture of Enamelled Goods.* H. Claus, Thale, Germany. Eng. Pat. 20,817, November 2, 1893.

In the methods formerly employed the spotting and marking of the metallic surface were obtained by oxidation of the steel or iron by the action of the acid in the enamel, such enamel consisting of silicate, borax, gypsum, and soda. This enamel requires very careful drying in a separate drying room, and the markings produced depend on the structure of the metal, a homogeneous material failing to give the variegated appearance which is desired. In this invention an enamel of the following composition is employed:—Felspar, 130; borax, 125; quartz, 70; soda, 25; saltpetre, 17; fluorspar, 10; antimony, 4 parts; cobalt,  $\frac{1}{2}$  part.

The metallic surface having been covered with the enamel, a mixture of equal parts of blue vitriol and green vitriol is powdered over the surface of the enamel. The whole is air-dried and then fired; the salts of copper and of iron descend through the enamel to the metal plate. Oxidation takes place at the surface of the metal through the action of the alkaline enamel upon the metallic salts, and the spotting is produced. The spotting thus produced is independent of the structure of the metal, but can be varied at will by using larger or smaller grains of the metallic salts. An additional advantage gained by the process is that careful drying in a separate drying room is not necessary.—V. C.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*The Testing of Portland Cement.* P. Cotte. Eng. and Mining J. 56, 722

For the test for fineness of grinding, three sieves are used, Nos. 50, 80, and 200. A well-made Portland cement will leave nothing on the 50 sieve, a residue of from 5 to 7 per cent. on the 80, and from 25 to 30 per cent. on the 200. Some will leave 15 to 20 per cent. on the 80, and 10 to 50 per cent. on the 200, but these should be rejected. The presence of particles of coal shows a careless selection of clinkers, whilst soft yellow grains show under-burned clinkers. The residue should be composed of nothing but hard black grains with sharp angles. The specific gravity of the cement is between 3.050 and 3.175. The most common adulterant is slag, but as its specific gravity is only about 2.8, any objectionable quantity might bring the specific gravity down below 3.050, which is the lowest that can be tolerated.

As to chemical composition, analyses of all kinds show that the constituents vary within the following limits:—

	Per Cent.
Silica .....	20.50 to 26.10
Alumina .....	5.20 „ 10.60
Iron oxide .....	2.10 „ 5.70
Lime .....	51.20 „ 67.31
Magnesia .....	0.33 „ 2.80
Sulphuric acid .....	0.20 „ 1.78

The relation between the silica and alumina on the one hand and the lime on the other constitutes the "degree of hydraulicity," which should not be below 0.43, but which should be raised to 0.46 when the cement is to be used on work in sea water. Oxide of iron should not exceed 4 per cent., and any cement having more than 3 per cent. of magnesia should be rejected. Magnesian cements give good tensile tests and look well for several months after use, but in course of time swelling takes place with almost irresistible force. Two or three per cent. of sulphate of lime can be present without injurious results, if soft water is used, but with sea water the presence of 1 per cent. of sulphuric acid would be dangerous.

The initial setting of Portland cement, gauged neat, should not begin before 30 minutes, and the final setting should not take place before 3 hours, a freshly-made cement usually setting in from 4 to 7 hours, although imported and old material will sometimes take 12 hours or more. Slow setting is almost essential, and a quick-setting cement, if good and well made, can be rendered slow-setting by exposing it to the air in thin layers. The test for stability is an important one, and a briquette, 24 hours after gauging, which is immersed in boiling water for 6 or 12 hours and shows no alteration, may be considered perfectly safe. Cold water is now rarely used for this test, the boiling water bringing out the effects of free lime very quickly. If the cement is mixed with a solution of calcium chloride (10 or 60 grains anhydrous salt per litre) and the cake immersed after 24 hours in the same solution, it will show signs of cracking in a few days if 3 or 4 per cent. of sulphate of lime is present.

The 24 hours' test for tensile strength has no value. Briquettes should be tested after 7 and 28 days, when, if good, they should withstand without rupture strains of 400 and 500 lb. per sq. in. respectively. This is with neat cement, but, as sand is generally mixed in practically, a test of a mixture of sand and cement is much more important. Three parts of cement and one of crushed quartz by weight is generally adopted, but the amount of water is not agreed upon. In Europe 10 per cent. is prescribed, and the mixture is compressed so as to bring out the full strength of the cement. In America the test is conducted more in accordance with the practical use, generally with more water and loose filling, but the results are not so concordant as in the European method. In Europe the crushing strength is sometimes considered more

important than the tensile, and tests are also made of the bending by bars of standard length, of the imperviousness and of adherence, but these have not yet been adopted in the United States.—A. W.

*The Preservation of Timber from the Attacks of Insects.*  
P. P. Dehérain. Comptes rend. 1893, **117**, 694—696.

THE author has observed that the sap-wood of trees used for timber is more subject to the attack of insects, such as boring worms, than the true wood, and farther, that amylaceous sap-wood is the kind most freely consumed by them. Besides this, he has found that the powder left by the consumption of the wood by these insects is free from starchy constituents. In order to deprive the timber of such constituents the plan of removing the bark at the foot of the tree, three or four months before felling, is found to be efficient, a mere ring a few centimetres in depth sufficing, provided that all growth below it be destroyed. Experiments with oaks from which the bark had been removed some months before felling, and others which had been decorticated at the time of felling, and a third series left with the full complement of bark, showed that the timber resisted in the order named. The author is of opinion that the amylaceous matter arising from the leaves is conveyed by the sieve tubes of the liber or inner bark (which run vertically), because the removal of the bark in a helical form is as efficient in securing the absorption of the starchy material as is an annular decortication. The best time to remove the bark is in the spring, the trees being felled in the following October.—B. B.

*The Weathering Properties of Sandstones.* W. Bolton.  
Dingl. Polyt. J. 1893, **289**, 43—48.

THE author points out that the usual criteria for the quality of building stones, such as their strength in compression, their absorptive power for water, and their behaviour when tested for weathering properties in the conventional manner, are not always conclusive. In particular, the compressive strength of the stone is seldom of much value in judging quality, as even inferior stones possess a crushing strength much above anything to which they are likely to be exposed in practice. Attempts to rank building stones according to their specific gravity have proved quite illusory, as no connection can be traced between this property and their mechanical value. A similar negative result has attended endeavours to find a relation between the tensile strength of the stone, its capacity for absorbing water and the force of expansion of the latter which is exerted in freezing. Methods directed to the determination of the capability of stones to resist those influences known collectively as "weathering," comprise the examination of the porosity of the stone as indicated by the quantity of water that it will absorb under standard conditions, the attack of its soluble constituents by hydrochloric acid and the observation of its behaviour when a liquid is caused to crystallise in its pores. With regard to the last-named test, the method formerly employed, which is known as Brard's test, and consists in repeatedly dipping the stone into a solution of sodium sulphate and allowing the salt to crystallise, is valueless as the assumption on which it is based, namely that expansion takes place during the crystallisation of the salt, is erroneous, the reverse being true. Dipping in water and freezing, many times repeated, is a more rational proceeding.

The author, however, prefers to base his judgment on the analysis of the stone, especial attention being directed to the nature of the substances serving as binding material to the particles composing the bulk of the stone. He quotes analyses of sandstones from the same source, some of which had formed part of buildings centuries old, while others had been recently quarried, and claims that he has traced a progressive alteration, which he ascribes chiefly to the action of alkaline sulphates upon the alumina, lime, and magnesia present in the stone, resulting in the formation of soluble sulphates of these bases, their removal from the stone, and its consequent deterioration. He advocates the

comparison of the behaviour of samples of sandstone when used for building purposes, with their composition as determined by analysis, in order to accumulate data for ascribing to each constituent its true influence on the quality of the stone.—B. B.

*On the Manufacture of Hydraulic Mortar in France and Germany.* H. Hanenschild, Thonind. Zeit. 1893, **17**, 418.

THE burnt material is spread in layers of 15 cm. thickness and moistened with water, then another layer is placed on top of this and again moistened. This is repeated until the total thickness attains 2 metres. The slaked mass is then sieved through revolving sieves having 600 meshes per sq. cm., the residue is worked up as Portland cement. These cements harden very slowly on account of the absence of alumina. The tensile strength of a mixture of one part of this cement with three parts of sand after seven days is only 3.3 kilos., after 28 days about 6 kilos., after five years from 25 to 40 kilos. The burnt material contains:— $\text{SiO}_2$ , 23.6;  $\text{Al}_2\text{O}_3$ , 1.4;  $\text{Fe}_2\text{O}_3$ , 0.8;  $\text{CaO}$ , 64.7;  $\text{MgO}$ , 1.4;  $\text{SO}_3$ , 0.5;  $\text{H}_2\text{O}$ , 7.6 per cent.

This product is very finely ground, leaving per sq. cm. on the 900 mesh sieve about 5 per cent., on the 5,000 mesh sieve about 27 per cent. of residue.—C. O. W.

*Improvements in the Manufacture of Artificial Building Materials.* F. W. Lübrmann, Düsseldorf. Eng. Pat. 20,004, December 1, 1892.

See under X., page 42.

*Improvements in and in the Method of Making Glazed Bricks, Tiles, and the like, and Glazing and Embellishing Walls and other Surfaces.* J. W. Martin, London. Eng. Pat. 19,797, October 20, 1893.

IN this invention the brick or tile is covered with cement, coloured or ornamented with pigments, and glass, roughened on one or both surfaces, is applied to the cement. The coloured cement is visible through the glass, and the effect of coloured marble or stone is thus imitated.—V. C.

## X.—METALLURGY.

*Changes produced in Iron by Permanent Deformation in the Cold.* G. Charpy. Comptes rend. **117**, 850—853.

WHEN a bar of iron is subjected to tension, and plottings made of the increments in length and tensile strain, it is found that a regular curve, analogous to that marked B in the figure, usually results; but with annealed iron and

steel the curve exhibits a zigzag like A. Iodide of mercury subjected to compression exhibits an analogous curve, as the yellow modification passes into the red form, when a certain pressure is reached (Mallard and Le Chatelier); hence it is probable that in the case of iron and steel an analogous molecular transformation takes

place. That this is so is now shown by studying the amount of residual magnetism left after 24 hours' standing after magnetising in bars previously subjected to degrees of tension corresponding with the points marked 1, 2, 3, and 4 respectively.

The figures obtained with bars of soft iron, extra soft steel (0·12 per cent. carbon), and semi-hard steel (0·5 per cent. of carbon) show that the magnetism varies much when the tensile strain corresponds with the rectilinear part of the curve, but is sensibly constant when this region is passed. Hence the effect of permanent deformation in the cold may be regarded as the developing of an allotropic transformation in iron and steel, such as the conversion of  $\alpha$ -iron into  $\beta$ -iron.—C. R. A. W.

#### *Zinc Smelting at the Bertha Works, Virginia.* E. C. Moxham. Eng. and Min. J. 56, 544.

THE smelting is carried out in 10 large Welsh-Belgian furnaces with 140 retorts in each. The process is conducted in the ordinary manner, the long-flame Pocahontas coal being used to fire the furnaces, while a semi-anthracitic coal is employed to mix with the ore in the retorts. The latter are made of selected fireclay, which must be capable of making a tenacious paste, can be worked without cracking, and must be fireproof, so that the retorts will not break or weaken when resting on their ends in the furnace at a white heat. The following are the analyses of two good clays, the first one being slightly the better because it is more elastic and will bend slightly before breaking, at a high temperature:—

#### *The F. L. Bartlett Zinc-Lead Process.* Abstract of report by E. W. Hawker. Eng. and Min. J. 56, 594.

THIS process, for the treatment of argentiferous zinc-lead sulphide ores, consists in separating the zinc and lead by volatilising them in the form of a zinc-lead fume, from which a marketable pigment is obtained, while the silver remains with the non-volatile metals, and is collected in a copper matte. Two methods of treating the ore are adopted, one for ores containing 25 per cent. of zinc and upwards, and the other for those containing 22 per cent. or less. The requisites for the process are (1) cheap flaming fuel, such as bituminous coal; (2) an iron ore, either oxide or pyrites, the latter being especially desirable if it contain silver; (3) a copper ore containing about 3 per cent. of copper for the formation of the matte to collect the silver.

In the first method the ore is crushed to pass a four-mesh screen, mixed with an equal bulk of fine coal, moistened, and charged in lots of 600 lb. into a furnace, of which the grate consists of perforated plates, the charge being spread on the grate to a depth of four inches. The burning is accomplished in about 4½ hours, by air being forced through the charge from below, and by a small quantity being also admitted above the charge, which is not touched during the operation. The sintered mass, containing the non-volatile metals, silver and some zinc, is then mixed with burnt

pyrites, copper ore, fluxes, and fuel in the requisite proportions, and smelted in a water-jacketed furnace of a greater proportional length than the ordinary blast furnace, when argentiferous copper matte is obtained, the bulk of the remaining zinc being volatilised.

In the second method the zinc ore is smelted directly, with the proper mixture of copper ore, fluxes, and fuel, in a special water-jacketed furnace with two rows of tuyers on each side, the upper ones being about 10 in. above the lower. The lower blast is preferably hot and the upper cold. The fuel consists of a mixture of coke and coal screenings, and is fed continuously with the ore in a layer from 12 to 18 in. deep. The lower blast plays upon the molten matter, scorifying it and volatilising all the lead and most of the zinc in the form of fume, which passes off through the unmelted portion of the charge, whilst the upper blast serves to keep up the necessary combustion and prevent the condensation of the volatile bodies. The argentiferous copper matte is tapped with the slag. The latter contains 6 to 10 per cent. of zinc, no lead, trace of copper, and about 1 oz. of silver per ton of ore treated. The matte contains 65 per cent. of copper and 250 oz. of silver per ton.

The fumes from all the furnaces are drawn into chambers by exhaust fans and forced through cooling conduits into long bags, through which the gases pass, leaving the solid contents of the fume behind. This is then refined by subjecting it to a low red heat and constant stirring, when all deleterious volatile matter is removed and a white pigment obtained containing 35 to 40 per cent. of oxy-sulphate of lead and 55 to 60 per cent. of zinc oxide.

In some ores there is a heavy loss of silver, in others very little, those containing copper or iron pyrites losing the least. Generally the salvage is between 70 and 85 per cent., but as much as 95 per cent. has been recovered. The loss should be confined to that in the pigment and that in the slags, but there is a further loss somewhere which at present is inexplicable.—A. W.

#### *Modern Processes for the Manufacture of Aluminium.* A. H. Bucherer. Zeits. ang. Chem. 1893, 17, 515.

See under XI., page 42.

#### PATENTS.

*Improvements in Effecting the Protection of Iron and Steel Surfaces, and in the Furnaces employed therein.* F. S. Barff, Kilburn, and G. Bower and A. S. Bower, St. Neots. Eng. Pat. 3304, July 28, 1881. (Reprint.)

A CHAMBER of cast or wrought iron, or other suitable material, and protected by a fire-brick casing, is heated externally by gas. The products of combustion pass around the chamber, and the waste heat is utilised for generating and superheating steam. The articles of iron or steel to be treated are placed inside the chamber and treated with this superheated steam, or, if desired, by carbonic acid, carbonic oxide, petroleum, or other hydrocarbon, while the chamber is maintained at a high temperature so as to produce a protective surface of magnetic oxide on the articles.—J. H. C.

*Improvements in and relating to the Preparation of Reagents for Working Gold and Silver Ores.* H. H. Lake, London. From Eloy Noriega, Mexico. Eng. Pat. 17,661, October 4, 1892.

THE reagent consists of a concentrated solution of protochloride of copper, or of the double protochloride of iron (ferrous chloride) and copper, prepared by submitting the ingredients, viz., sulphate of copper, chloride of sodium, sulphuric acid, and water, to the action of steam and using metallic copper to neutralise the excess of acid. Ferrous chloride prepared in a similar manner may be also used with or without the addition of cyanide of copper.—J. H. C.

*Improvements in the Manufacture of Artificial Building Materials.* F. W. Lüthmann, Düsseldorf. Eng. Pat. 20,004, December 1, 1892.

BLAST-furnace slags are re-heated in a reverberatory furnace with suitable additions, of limestone, dolomite, clay, quartz, oxide of iron, &c., or with other kinds of slag. The mass is then removed from the furnace and allowed to cool. In most cases, in carrying out the process, it is advantageous to add to the fused mixture a few per cents. of oxide of iron in any convenient form. Data and a formula are given for calculating the proportions of lime and slag that should be used.—J. H. C.

*Improved Application of Aluminium and its Alloys.* W. R. Taylor, Rochester. Eng. Pat. 22,843, December 12, 1892.

THIS invention consists in the application of aluminium or its alloys to the manufacture of brewers' casks, jugs, earboys, water tanks, mineral water bottles and siphons, culinary utensils, milk cans, butter firkins, fermenting and evaporating pans, cocks and taps, pumps and bar fittings, &c. In the case of large vessels, the metal sheet is strengthened by hoops or wooden staves or by applying a layer of wood pulp or other suitable material in a mould.—W. J. P.

*Improvements in the Manufacture of Steel or Wrought-Iron.* P. M. Justice. From the Société anonyme des hauts fourneaux et forges de Dudelange, Grand Duché de Luxembourg. Eng. Pat. 23,286, December 17, 1892.

IN the manufacture of steel and ingot-iron, the metal is carburized in the casting ladle by means of briquettes made of carbon with or without the addition of lime (Eng. Pat. 17,613, 1890, this Journal 1891, 262). The patentee claims protection for the use of such materials in a pulverised form instead of in briquettes. The carburization may be performed by addition of the mixture to the molten metal whilst in the Bessemer converter, ingot moulds, or whilst running into the moulds or furnaces.—W. J. P.

*Improvements in the Purification of Iron.* E. H. Saniter, Wigan, Lancashire. Eng. Pat. 23,534, December 21, 1892.

THIS patent deals with improvements on the processes described in (Eng. Pat. 8612, 8612A; this Journal 1892, 1013 and 1014), and 17,692 of 1892 (this Journal 1893, 844). Mixtures of calcium chloride and fluoride with lime or other oxide, a hydrate or carbonate of an alkaline earth are placed in the casting ladle or other receiver or furnace and the molten iron run on to it with the object of purifying the latter metal. Other chlorides or sodium borate may be used if found desirable. If a large ladle be employed the mixture is best confined in a well at the bottom so that it shall rise slowly through the molten metal.—W. J. P.

*Improvements in the Recovery of Iron from the Ferruginous Residue left in the Production of Amine Bases.* S. S. Bromhead. From Landshoff and Meyer, Grünau, Germany. Eng. Pat. 23,639, December 22, 1892.

THE ferruginous residue obtained in the commercial production of amine bases is heated in a muffle and treated with steam at a red heat. On increasing the temperature to near the melting point (900° C.) the iron is partially reduced by the carbonaceous substances contained in the residue; the reduction is completed by covering the mass with charcoal, coke, or pitchy residues, which do not contain sulphur or by passing carbonic oxide over it. The cooled reduced metal is then sieved and again employed for reduction.—W. J. P.

*A Process for the Elimination of Sulphur from Molten Iron or Steel.* H. J. Phillips, Ebbw Vale. Eng. Pat. 1437, January 23, 1893.

THE molten metal whilst contained in a converter is mixed with blast-furnace slags or manganiferous slags of all kinds, glass, potassium, sodium, calcium, or barium silicates, silicates of alumina or iron, and all other silicates, individually or severally, mixed with basic materials, forming a highly basic slag, which will melt, thereby increasing the chemical affinity between the base and the sulphur contained in the iron; lime, potash, oxide of iron, dolomite, limestone, baryta, soda, alumina, or any cheap base may be used; fluor-spar, rock-salt, or powdered coke may also be added at times with advantage. After puddling or other mixing the iron is run off, the slag being retained by means of dams.—J. H. C.

*Improvements in or relating to the Tinning of Articles made of Cast Iron.* A. J. Boulton, London. From Messrs. Wolf, Netter, and Jacobi, Berlin. Eng. Pat. 2349, February 2, 1893.

THE cast-iron is coated electrolytically with iron and nickel or iron and cobalt, before the coating of molten tin is applied in the ordinary way.—J. H. C.

*Improvements in or relating to the Conversion or Purification of Iron and Steel.* A. J. Boulton. From W. A. Koueman, C. F. Singer, and A. F. Hatch, Chicago, U.S.A. Eng. Pat. 12,588, June 27, 1893.

THE inventors employ a tall fire-brick shell some 30 feet or more in height for the smelting of metallic ores. This furnace is fed with coal and some suitable flux through a hopper at the top, so that the fuel at the upper part of the firebed undergoes distillation; the gas thus formed is conducted off and led again into the furnace below the top layer of fuel, from which it distilled. Here the gas comes in contact with the molten metallic ores or slags which have been charged into the furnace with the fuel, and have sunk down as the fuel burnt, until reaching a portion of the furnace at which an air-blast enters, they melt and percolate through the underlying incandescent fuel; the metal is reduced by the gas and passes out at the lower part of the furnace. Metallic ores or slags may be treated by this process, and scrap iron may be converted into a highly carburized iron.—W. J. P.

*An Improved Process for Producing on Steel, Iron, or other Metals a Durable and Smooth, either Glazed or Dull, Black Surface.* W. T. Thompson, Liverpool. From W. Kiesel, Ludwigsbürg, Germany. Eng. Pat. 20,024, October 24, 1893.

THE material is pressed or worked in the cold into the desired shape, smoothed and coated with balsam of sulphur after it has been heated and boiled in hydrochloric acid. The heating and immersion may have to be repeated at various stages of the work.—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*Modern Processes for the Manufacture of Aluminium.* A. H. Bucherer. Zeits. ang. Chem. 1893, 17, 515—517.

THOSE methods which consist essentially in the electrolysis of alumina dissolved in fused cryolite, have notable advantages over such as depend on the principles formerly in vogue. The plan in question originated in the laboratory researches of Deville, who in 1859 described a process by which aluminium was prepared by the electrolysis of fused

eryolite, the composition of the bath being maintained by the dissolution of anodes of carbon containing alumina. It is probable that Deville was led to try this method by analogy with his successful process for the manufacture of aluminium by purely chemical means. Just as by the action of chlorine on a heated mixture of alumina and carbon, aluminium chloride is formed, so it might be expected that aluminium fluoride would be produced by the action of fluorine set free by the electrolysis of eryolite upon the mixture of alumina and carbon constituting the anode. In this early process the heat requisite for maintaining the fluidity of the bath was supplied from without. The reasons for the non-utilisation of this method until recent times, are to be found in the facts that an externally heated vessel is soon destroyed under the prevailing conditions; that the content of the bath in alumina cannot be maintained with a difficultly soluble anode of high resistance, such as one composed of alumina and carbon; and that the cost of current was formerly too high. In modern practice all these drawbacks are overcome by the use of pure carbon anodes, by feeding alumina direct to the bath, by internal heating due to the electrolytic process itself, and by the use of cheap current.

Inasmuch as the output of aluminium for a given consumption of energy is dependent on the reactions taking place in the electrolytic bath, the consideration of the nature of these reactions is of primary importance. In processes in which alumina is fed into a bath of eryolite or similar halogen salt, it has been asserted that the main action of the current consists in the electrolysis of the alumina. The author, however, considers that, taking into account the calculated E.M.F. corresponding with the heats of formation of the oxides and fluorides of sodium and aluminium, and also adopting the modern hypothesis of the dissociated condition of electrolytes, the fundamental reaction is the electrolysis of sodium oxide, followed by the liberation of aluminium from its fluoride by the action of the sodium already produced. In support of this view he adduces the fact that when a bath of pure eryolite is electrolysed, on reaching a certain current density sodium is set free, because the quantity of aluminium fluoride is insufficient to react at once with the alkali metal. On increasing the proportion of aluminium salt, however, almost the theoretical amount of aluminium for the current passing, is obtained.

In the Minet process the use of a bath of aluminium fluoride and sodium chloride in place of one of eryolite is claimed. The author finds by experiment that aluminium fluoride is not soluble in sodium chloride (both salts in the fused state), and that the first effect of the electrolysis of such a mixture consists in the production of chlorine and sodium, the latter acting on the aluminium fluoride and liberating aluminium. The ultimate result is the formation of a eryolite bath, prepared in a manner far from economical. When once the eryolite bath has been prepared, the addition of alumina transforms the sequence of reactions into that proper to the Hall or Héroult process.—B. B.

*Action of Certain Metals on Acid Solutions of their Chlorides.* A. Ditte and R. Metzner. *Comptes rend.* 1893, 117, 691—694.

THE author has studied the well-known phenomenon of the formation of crystals of metallic tin on the upper part of a rod of the metal dipping in a solution of stannous chloride, made acid with hydrochloric acid, upon which rests a layer of water. The formation of the crystals does not take place in a homogeneous solution of stannous chloride, and the deposit is most abundant at the plane of junction of the liquids, decreasing with the distance therefrom; as the distance increases the character of the deposit changes, the tin becoming grey and spongy, and finally tailing off to a black powder. The usual explanation is that the phenomenon is one of electrolysis, and this is borne out by the possibility of replacing the tin above the plane of junction of the liquids with a rod of platinum, upon which crystallisation takes place as readily as upon the tin. Moreover, crystallisation can be induced at any predetermined spot on the upper part of the rod by making the liquid at that spot a better conductor by introducing a little stannous chloride

at the point selected. Another indication in the same sense is afforded by the observation that when two bars of tin are placed one above the other without contact, the production of crystals on the upper bar takes place as soon as the progress of diffusion has transferred sufficient tin salt to the upper layer of liquid. The solution of a portion of the tin is of course a necessary preliminary to its deposition elsewhere, whence it follows that no crystallisation occurs when the lower part of the bar is immersed in a neutral solution of stannous chloride.

The deposition of crystals of cadmium can be effected in a similar manner, but in the case of a metal like zinc, easily soluble even in dilute hydrochloric acid, the formation of crystals is not observed. Nickel fails to yield a deposit, this being attributed by the author to the ease with which the metal is covered by a film of hydrogen, which cuts it off from contact with the acid liquid. Metals like bismuth and antimony, which are not appreciably attacked by dilute hydrochloric acid, give negative results.—B. B.

*The Influence of Frictional Electricity upon the Formation of an Amalgam.* G. Staats. *Ber.* 1893, 26, 1796—1797.

IN order to ascertain the influence of electricity of high tension upon the process of formation of an amalgam, a small Leyden jar was used, covered on the outside with tinfoil, and containing mercury to the same height as the outer covering, and having a steel wire terminating in a small silver disc as the means of connection between the charging knob and the mercury in the interior, and the weight of this silver disc, before and after the experiment, was determined. In a second series of experiments, the steel needle with its disc was exposed to a stream of sparks from the conductor of an influence machine for 60 seconds, and then dipped in mercury for a few seconds, and weighed after removal. The mean result of the experiments showed that 23.07 per cent. of amalgam was formed without the use of electricity, and 72.09 per cent. when electricity was employed. In all cases superfluous mercury was shaken off the amalgamated disc before weighing.

—B. B.

*Progress in Electrometallurgy.* *Dingl. Polyt. J.* 1893, 289, 129—135.

*Aluminium.*—One of the most noteworthy features in the recent improvements in the production of aluminium, is the increased purity of the metal, which is said to be procurable with as little as 0.1 per cent. of foreign matter, though trustworthy analyses show 0.8 per cent. to 1.0 per cent. as a more usual amount in the best samples. An indication of the rise in the rate of production of late years is afforded by the increase in the output of the works at Neuhausen, which amounted to 40,538 kilos. in 1890, 168,669 kilos. in 1891, estimated at 300,000 kilos. for 1892, and is expected to reach 1,000,000 kilos. in 1893.

The best methods at present in use for the manufacture of aluminium consist in the electrolysis of a fused electrolyte, e.g. alumina, older processes necessitating the intermediate manufacture of sodium, having been exposed thereby to severe competition, which has caused many efforts to be made to lower the cost of production of the alkali metal (*cf.* this Journal, 1893; 1887, 174). The preparation of the alumina which is used in the Héroult furnace is effected by fusing bauxite with sodium carbonate, extracting the sodium aluminate formed, and precipitating with carbon dioxide, by which means it is obtained in a state of sufficient purity for the purpose in hand. According to Grabau's patent a mixture of aluminium fluoride and sodium carbonate is used as the electrolyte, sodium fluoride and ultimately eryolite being formed as the process progresses. An oxyfluoride, to which the formula  $Al_2O_4F_2$  is assigned, can be substituted for aluminium fluoride. Equations representing the changes said to occur during electrolysis, are quoted.

Bueherer's patent relates to the use of double sulphides of aluminium and the alkalis or alkaline earths, dissolved

in a bath of fused alkaline chlorides and electrolysed (cf. this Journal, 1893, 272). A similar process has been protected by the Aluminium Co. of Neuhausen. The following advantages are claimed for processes of this type:—

(1.) The carbon anode is not attacked, as sulphur is eliminated thereat instead of oxygen, and the temperature is too low to permit of the formation of carbon bisulphide.

(2.) The production of aluminium requires a comparatively low voltage (2·5—3 volts).

(3.) Short-circuiting is avoided, as the aluminium is of higher specific gravity than the bath, and sinks to the bottom of the vessel.

(4.) The sulphur appearing as vapour at the anode can be recovered and utilised.

**Tungsten.**—A method for the preparation of tungsten has been patented by Krieg. It consists essentially in preparing the chloride, transforming this into tungstic acid, and reducing the latter to metal, the first and last operations being performed by electrical means. The preparation of the chloride is effected by using electrodes composed of a mixture of scheelite or wolfram and carbon for the production of an electric arc in the presence of chlorine, the chlorides of the metals present in the ore being thus obtained as a sublimate. Tungstic acid is separated from the product by treatment with hydrochloric acid, by which means tungsten chloride (and silicon chloride) is decomposed and ferric chloride, aluminium chloride, &c., are dissolved. The tungstic acid is freed from gelatinous silica by elutriation, made into electrodes with carbon, and reduced to metal in a closed vessel.—B. B.

## PATENTS.

*Improvements in the Treatment of Ores and Recovery of the Metals contained therein, and Appliances therefor.* F. G. Fuller, London. Eng. Pat. 20,025, November 7, 1892.

FREE-milling and some refractory ores after proper crushing, and sometimes after concentration, are placed in an amalgamating trough, the ends of which are made of conducting material, whilst the sides and bottom are of insulating material. A current of electricity is made to pass through the ore which is caused to move forward between a series of electrically excited amalgamating plates and in contact with a sufficient quantity of mercury or other suitable chemical reagents, such as a chloride of the alkalis, nitric acid, nitric acid vapour and water, sulphuric acid, a bi- or persulphate, &c., together or separately, and heated or not as required. The amalgam is collected, or the solutions produced are drawn off for separate treatment, by chemical re-agents, electricity, or other suitable methods.

In treating refractory ores a series of stationary or revolving "furnaces" is employed. The ores properly prepared by crushing or by a previous roasting are placed in these "furnaces" and heated from hot-air generators connected by means of suitable flues and controlled by dampers. Steam is also supplied, or acid fumes from the roasting of pyrites, the distillation of nitrates or other convenient means. The ores so treated are then leached with water or chemical solutions and the liquors so obtained are treated by any suitable methods for the separation of their contained metals.—J. H. C.

*Improvements in the Preparation of Chromic Acid and in the Extraction of Pure Acids from Alkaline Salts.* E. Placet and J. Bounet, Paris. Eng. Pat. 22,819, December 12, 1892.

See under VII., page 37.

*An Improvement in Plates for Secondary Batteries.* A. Hough, Forest Hill, Surrey. Eng. Pat. 23,750, December 23, 1892.

According to this invention the plates for secondary batteries are constructed as follows:—A good conducting wire, preferably copper, is coated with lead by drawing it through a bath of lead which is not in a fluid condition, but nearly at its setting point. The wire thus coated is drawn down to a suitable gauge, and formed into a gauze network, to constitute the frame of a plate. The meshes of this frame are filled in and covered with lead oxide, preferably a mixture of coarse-flake and finely-ground litharge, applied in a dry state. The plate is then placed between sheets of felt, or the like, moistened with dilute sulphuric acid, and after about six hours it is removed from the felt and left to dry and set for about 12 hours. The litharge is then reduced to spongy lead in the usual manner.—G. H. R.

*Improvements in Apparatus for the Making or Manufacture of Caustic Soda or Caustic Potash, being a Method of passing the Chlorine and Sodium Gases to the Receiver.* F. W. Petrie, Rochdale. Eng. Pat. 472, January 10, 1893.

See under VII., page 38.

*Improvements in Platinised Electrodes.* H. T. Barnett, London. Eng. Pat. 757, January 13, 1893.

SILVER, carbon, or any other suitable material may be used to construct the electrodes of, and a convenient method of manufacture by which the conducting support is a compound, solid, cylindrical, and textile mass, is as follows:—Electric light carbon rods are pasted and dried, and lightly bound with freshly-pasted strips of cotton velvet that have been previously pasted and dried. They are dried slowly in an air-current, and when on the pile are sprayed with chloride of platinum solution, after which they are quickly dried in an oven, and then carbonised, while packed in charcoal dust, in a gas or other muffle furnace.—G. H. R.

*Improvements in connection with Carbon Electrodes.* H. T. Barnett, London. Eng. Pat. 758, January 13, 1893.

This invention consists of the combination of an electrode formed of a number of fine carbon projections outstanding from a carbonaceous or metallic support, and one or more guarding portions attached to, or formed of the substance of the conducting support. The outer surface of the guarding portions is coated with an electricity insulating cement, enamel, or other suitable material.—G. H. R.

*Improvements in or connected with the Manufacture of Electrodes for Electric Accumulators.* C. Pollak, Frankfort-on-Main, Germany. Eng. Pat. 813, January 13, 1893.

THE object of this invention is to effect the more rapid formation of electrodes of the so-called Planté type, by using porous compressed lead obtained by a wet process, by stirring carbonate of lead into a paste with caustic alkali, then reducing this paste (after imparting the necessary shape to it by means of suitable supports, if necessary, and it has become dry) in an alkaline solution by electrolysis, and finally compressing the porous lead thus formed, to a greater or less degree, immediately after the reducing process, and whilst it is still wet.—G. H. R.

*Improvements in Electrolytic Apparatus.* C. Hanbury, London. Eng. Pat. 8176, April 22, 1893.

THIS invention relates to improvements in the construction of electrolytic tanks, and consists in fixing near the opposite ends, or sides, partitions which cut off two narrow portions forming transverse chambers. Each of these chambers is divided into two by a horizontal watertight partition. Between these chambers, at the opposite ends or sides of the tank, and at right angles to them, porous diaphragms, each with an anode and cathode, are fixed so as to form watertight compartments, which contain alternately (except in the first and last) two positive and two negative electrodes. In the space corresponding to every other compartment, a free aperture is made near the top of the partition into the upper transverse chamber at one end of the tank, the lower edge of which aperture dips just below the intended level of the electrolyte. The partition at the other side is similarly perforated near the top in the spaces corresponding to the other alternate compartments. Free openings are made at the bottom of each transverse partition between alternate compartments and the lower transverse chamber, these openings alternating with those in the upper series. The cover of the tank fits closely, and provision is made for drawing off the gas evolved, and for the circulation of the electrolyte.—G. H. R.

*Improvements in Electro-plating.* E. de Pass, London. From H. Thofehn, Paris, France. Eng. Pat. 10,095, May 20, 1893.

ACCORDING to this invention, in order to obtain a smooth deposit of metal upon a cylinder, or a moulded or shaped article, rotating in an electrolytic bath, the surfaces to be plated are showered with a stream of jets, under pressure, of the electrolyte, which acts either continuously or intermittently during the whole of the electrolytic operation. The showering may be effected by means of perforated or slotted tubes or discharge pipes, which may advantageously receive a reciprocating motion. To prevent the electrolyte becoming disturbed during the action of the current, or jets, directed on to the cathodes, the anodes are placed at a suitable distance from the bottom of the tank. The electrolyte is drawn off from the bottom of the tank, and delivered into a reservoir, wherein it is cleansed from impurities, and afterwards restored to its standard strength, and is then again showered on to the cathodes, a constant circulation of the electrolyte being thus kept up.—G. H. R.

*Improvements in Secondary Voltaic Batteries.* E. J. Chubbe and A. W. Southey, London. Eng. Pat. 10,765, June 1, 1893.

ACCORDING to this invention the negative element consists of a pasty mass of peroxide of lead resting on the bottom of a cell or container, of dish or tray form, which is provided with a conducting plate of lead or an alloy of that metal, coated with gold or platinum to prevent oxidation, and embedded in and wholly covered by the pasty mass, except a narrow strip which serves as a contact piece, and is bent so as to pass out of the cell.—G. H. R.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Macassar Oil.* R. Glenk. Amer. Journ. Pharm. 65, 528.

A SPECIMEN of this oil, obtained from the seeds of *Schleichera Trijuga*, Willd (Sapindaceæ), and sent from Mirzapoor, Hindostan, has been examined by R. Glenk, who describes it as a yellowish-white semi-solid substance, having a faint odour of bitter almonds, and a specific gravity of 0.942. It probably contains hydrocyanic acid, and its

mildly acid taste may be ascribed to partial rancidity. An acid reaction was indicated with litmus paper, and the oil was completely liquefied at 28° C., congealing again at 10°. It was readily saponified by sodium hydrate, even at a low temperature, forming a white, hard soap. With nitrous acid it assumed an orange-red colour, and became viscid, but did not appear to solidify. Concentrated sulphuric acid acquired a reddish-brown colour on addition of the oil. Chloroform, ether, carbon bisulphide, benzene, benzine, and the fixed and volatile oils freely dissolve the oil, but alcohol only slightly affects it.

*Detection of Paraffin and "Lubricating Oil" in the Distillate obtained under Pressure from Tallow Oil.* C. Engler and L. Singer. Ber. 1893, 26, 1449—1451.

THE fact that neither paraffin nor "lubricating oil" was detected in the distillates obtained under pressure from natural glycerides and from the higher fatty acids, and which were examined in the author's laboratory, has been frequently urged against the theory of the formation of petroleum from the remains of animal fat. The authors have in consequence again taken up the subject with special reference to the detection of the above-named substances, and they have succeeded in separating solid paraffin and in obtaining a fluorescent and viscous "lubricating oil." The paraffin was obtained in the form of a white crystalline mass melting at 49—51°.—A. K. M.

*Adulteration of Olive Oil.* V. Oliveri, Le Staz. speriment. agr. ital. 1893, 24, 387.

THE refraction coefficient, saponification number, and iodine absorption of 106 pure olive oils were ascertained and compared with those of other oils. The following are the results:—

	Refraction Coefficient.		Saponification Number.		Iodine Absorption.	
	Mini-mum.	Maxi-mum.	Mini-mum.	Maxi-mum.	Mini-mum.	Maxi-mum.
Olive oil .....	0	2	190.5	195	79	82.2
Cotton-seed oil .....	18		191	195	104	108
Sesame oil .....	15.5		189	190.5	105	107
Colza oil .....	26.5		177	178	99	100
Peanut oil .....	7.5		191	196	101	105
Poppy-seed oil .....	28.5		192	195	133	138

THIS shows that by means of the oleo-refractometer, admixtures of not too small quantities of any of the above oils with olive oil can be detected, as the refraction coefficient would be above 2. Peanut oil is, however, an exception, since a mixture of 25 per cent. of this and 75 per cent. of olive oil with a refraction coefficient 0.25 would give a mixture the refraction coefficient of which would not be above 2. But even in this case the high iodine absorption would betray the adulteration.—C. O. W.

### PATENTS.

*An Improved Process for Treating and Purifying Sod and other Oils, and Apparatus therefor.* F. N. Turney, Nottingham. Eng. Pat. 1319, January 21, 1893.

For the purification of sod oil (the refuse oil after treatment of chamois leather with cod and other oils) containing water, colouring matter, and impurities derived from the skins, the oil is agitated with a solvent, such as petroleum spirit or carbon bisulphide, and the mixture is allowed to stand. The water and impurities then settle out. The supernatant mixture of oil and solvent is drawn off and distilled, and the solvent condensed for use over again, leaving the purified oil in the still. This oil is useful for currying purposes, and is said not to colour or stain the goods. The process is applicable to the purification of lubricating and other oils.—J. J. K.

*Improvement in the Manufacture of Emulsions.* H. Helbing, London. Eng. Pat. 8196, April 24, 1893.

DEXTRIN is the emulsifying agent employed for oils and liquids which will not mix with water. It is made into a thin paste with water, compounded with the oil, and vinegar is then stirred in to form a homogeneous mass; or the vinegar may be first mixed with the dextrin and the oil added afterwards. Medicinal and flavouring preparations may be mixed with the emulsion.—J. J. K.

*Improved Method of Separating Fats.* M. Ekenberg, Stockholm, Sweden. Eng. Pat. 17,565, September 18, 1893.

By the process claimed, the separation is effected of three different fats and cholesterol contained in neutral wool fat, the melting point of which varies between 38° and 46° C., being generally above 40° C. Wool-fat is melted, cooled slowly to 35° C. in moulds to form thin tablets or cakes, and pressed in hot presses or centrifugal machines; all molten fat at this temperature flows out. The same operation is then repeated at 45° C. The products obtained are, at 35° C. a fat containing about 60 per cent. of cholein melting at 25°–29° C.; at 45° C. a fat containing about 60 per cent. of cholepaluin, melting at 37°–38° C.; the residue in the press consisting of a mixture of cholecerin and cholesterolin, containing 60 per cent. of cholecerin, melting at 49°–55° C. Solvents, such as volatile hydrocarbons, fat oils, and fatty acids, added to the wool-fat are said to facilitate the production of the three fats, and may be separated afterwards; that of the fat oils and acids by saponification with alkali. The cholein may be used for lubricating, the cholepaluin in the manufacture of soap and candles, and the cholecerin as a substitute for beeswax.

—J. J. K.

*An Improved Fat Emulsion and Method of Producing the same.* M. Ekenberg, Stockholm, Sweden. Eng. Pat. 17,566, September 18, 1893.

This relates to the production of an emulsion from cholein, a fat obtained by means described in the preceding patent, No. 17,565, which has the property of forming emulsions with water containing 30 per cent. or more of fat. The melted fat, heated to about 40° C. in a centrifugal mixing apparatus, is mixed with a small quantity of water, allowed

to stand for some hours to lower its temperature to 25°–30° C., and mixed with a quantity of water sufficient to obtain the desired proportion of fat and water. This emulsion may be used as a pomade, as a means of softening leather, or to preserve raw hides.—J. J. K.

*Improved Apparatus for and Process of Making Soap.* M. J. Palmer, Toledo, Ohio, U.S.A. Eng. Pat. 19,298, October 13, 1893.

The saponification is effected in a vacuum chamber, heated by steam, assisted by a revolving agitator, which intimately commingles the fatty matter and alkali. The product is then ejected into a vat and subjected to the action of the electrical current, which disintegrates the fatty globules therein, and effects a complete and rapid saponification, obviating the necessity of time and storage, for ageing the soap.—J. J. K.

## XIII.—PAINTS, PIGMENTS, RESINS, VARNISHES, INDIA-RUBBER, Etc.

### (A.)—PAINTS, PIGMENTS.

*Antimony Blue.* G. Sebor. Casopis pro prumysl Chemicky, 1893, 216.

THE author attempted to find a practically workable method for the preparation of this blue, which was discovered by Boettger in 1871. Sulphide of antimony is dissolved in concentrated hydrochloric acid, and the solution filtered through asbestos. The moderately concentrated solution is heated to the boiling point and mixed with a concentrated solution of potassium ferrocyanide. A small quantity of potassium chlorate or nitric acid is then added and the whole well boiled. The mass is then filtered and washed, and subsequently dried. A very deep fine blue pigment is obtained in this manner. Another blue is obtained by mixing the solutions of antimony trichloride and potassium ferrocyanide without regard to their concentration, and subsequently adding a large excess of water. This yields a fine pale blue. An antimony blue, as pure as it could be obtained, gave the following analytical numbers: Fe, 30.28 per cent.; Sb, 2.422 per cent.; H<sub>2</sub>O, 5.828 per cent.; Cl, 0.712 per cent.; O, 0.323 per cent.; CN, 60.435 per cent. This blue behaves towards acids like ordinary Prussian blue; it is not affected by cold solutions of the caustic alkalis or of ammonia, but by using hot solutions, it is destroyed. It differs from Prussian blue in being insoluble in a solution of ammonium oxalate or tartrate.—C. O. W.

### PATENT.

*A New or Improved Protective Paint.* T. Cohn, Berlin. Eng. Pat. 19,444, October 16, 1893.

This paint consists mainly of oxide of lead, common salt, and a soluble salt of a suitable heavy metal, the whole being stirred up with a little water, washed, and finally ground with oil or varnish. "The oxide of lead combines with the common salt and forms chloride of lead and hydrate of soda. The latter precipitates the oxides or the hydrates of the heavy metallic salts, and thereby forms, with the fatty acids contained in the oils or varnish, saponaceous products. The latter become dissolved in the free oil, and give the paint its elasticity." Convenient proportions are 10 parts of oxide of lead, 2 parts of common salt, enough water to form a thin paste, and 5 parts of chloride or sulphate of zinc. To produce various colours, salts of various other metals, such as copper, iron, &c., may be substituted for the zinc salt.—A. G. B.

## (B.)—RESINS, VARNISHES.

*Kauri Copal Digging in New Zealand.* Chem. Ind.  
1893, 16, 137—138.

Kauri copal is the resin of *Dammara Australis*, and the occurrence of this fir is limited to the province of Auckland, where it appears to have been growing for many thousand years. This resin is of very great importance for the manufacture of varnishes and lacquers, but up to a few years ago, only the fossilised resin was employed for this purpose, the fresh resin being almost valueless. In recent times this resin is also employed for certain purposes. The fossil resin is obtained by digging, mostly on land where no Kauri firs exist at present. The resin is frequently found in quantities of from 50 to 100 lb. together, sometimes even forming blocks weighing from 2 to 4 cwt. The first colonists in Auckland found this resin in enormous quantities when tilling the soil. Its value then being unknown it was burnt as fuel. The first shipment to London of 300 tons was made in 1815, and the resin being found unsaleable, it was sent to America, where its value for the manufacture of lacquers was discovered. Since then the exports have been steadily increasing, and amount to nearly 9,000 tons per annum at present. In some places the resin is found in beds 10 feet in thickness, and till lately the ploughing of native soil was frequently found to be a very remunerative operation on account of the resin brought up by the plough shares.—C. O. W.

*On Xanthorrhoea Resins.* M. Bamberger. Monatsh.  
Chem. 1893, 14, 333.

XANTHORRHOEA resins, which are known in commerce as "Akaroid resin," "Botany Bay resin," "Grass tree gum," "Nut resin," have been repeatedly investigated by Liechtenstein, Laugier, Trommsdorff, and Widmann. Steinhöuse discovered in the yellow resin cinnamic and benzoic acid, and by treating it with nitric acid he obtained large quantities of picric acid. Hlasiwetz and Barth obtained from the same resin, by fusing it with caustic potash, large quantities of para-hydroxybenzoic acid, resorcinol, and a double compound of protocatechuic acid with para-hydroxybenzoic acid and catechol.

*I. Yellow Xanthorrhoea Resin (Xanthorrhoea hastilis Sm.)*—The acid number, saponification number, and iodine number were determined by Schmidt and Erban's method. The figures given refer to resin purified with alcohol, unless stated differently. Acid number, 132—133; saponification number, 220—225; iodine number, 86; methyl number, crude resin, 27·66—28·97; purified resin, 34·73; crude resin (Amsterdam Exhibition), 27·29. Boiling water extracts from the yellow resin 10 per cent. of paraeumaric

acid and smaller quantities of parahydroxybenzaldehyde, a body resembling vanillin, and benzoic acid with 1 per cent. of cinnamic acid.

*II. Red Xanthorrhoea Resin (Xanthorrhoea Australis).*—The acid and saponification numbers of this resin cannot be estimated owing to the intense red colouration of its alcoholic solution. The iodine number of the purified resin was found to be 105·5. Methyl number, crude resin, 60·3—60·9; purified resin, 71·12. Carbonyl number, 0·07. Boiling water extracts from this resin about 2 per cent. of paraeumaric acid, a substance resembling vanillin, and para-hydroxybenzaldehyde.—C. O. W.

*Gardenia Resin.* E. Heckel and Schlagdenhaufen.

Répert. de Pharm. 1893, 49, 145.

THE leaf buds of the New Caledonian *Gardenia G. Oudup Vieil*, *G. Aubryi Vieil*, and *G. Sulcata Gaertn.* possess a protective coating of green resin which is chewed by the natives. Also when dissolved in brandy it is used for dressing wounds and ulcers on account of its antiseptic properties. The resin is, however, chiefly employed for caulking and making water-tight the canoes of the natives. It is insoluble in water, easily soluble in ether, acetone, alcohol, and chloroform. On evaporation, the ethereal solution leaves an opaque, yellow mass, which on exposure to the air hardens completely within three weeks. In its composition and reactions with metallic salts, the resin resembles the tannins. This resin is likely to become very useful both medicinally and as a basis for varnishes.—C. O. W.

## (C.)—INDIA-RUBBER, &amp;c.

*The Manufacture of India-Rubber Waterproof Cloth.* C. O. Weber. Zeits. ang. Chem. 1893, [21], 22.

See under V., page 33.

*India-Rubber Substitutes.* R. Henriques. Chem. Zeit.  
1893, 17, 634—638.

INDIA-RUBBER substitutes prepared by boiling fatty oils with sulphur or by treating them in the cold with chloride of sulphur are distinguished in the trade by the names "brown" (black) and "white substitute" respectively. These two products are entirely different in their composition, they possess a slightly penetrating, oil-like odour and are very insoluble in all the usual solvents. The "white substitute" is distinguished by the high proportion of chlorine it contains, and which can neither be removed by boiling with water nor with acids. This substitute is obtained by treating vegetable oils with chloride of sulphur. Analyses of a number of different substitutes of various descriptions gave the following results:—

	Commercial Products.						Linseed Oil Substitutes from		Colza Oil Substitutes from		Poppy Seed Oil Substitute, from Oxidised Oil.	Castor Oil Substitutes.		Substitute from Oxidised Cotton Seed Oil.

The sulphur and chlorine were estimated by dissolving the substitute in fuming nitric acid in the presence of silver nitrate, subsequently fusing with sodium nitrate, dissolving in water and filtering. The sulphuric acid was estimated in the filtrate, the insoluble silver compounds containing the chlorine were estimated by titration with solutions of sulphocyanide and silver. The presence of considerable quantities of chlorine in the white substitute explains the low iodine absorption of these products, although it is not quite as low as had been believed and as will be found by leaving the substitute for 12 hours in contact with Hübl's iodine solution. On saponification with alcoholic potash, the chlorine is completely eliminated from the substitute, whilst the sulphur remains in combination with the fatty acids. The amount of fatty acids contained in the substitute appears rather small. It was however found, that on precipitating the fatty acids from the aqueous solution of the saponified substitute, the mother-liquor, which contains large quantities of hydrochloric acid, contained neither sulphuretted hydrogen, sulphurous, nor sulphuric acids in more than traces. On concentration, until hydrochloric acid begins to escape freely, the liquid becomes turbid and now contains large quantities of sulphuric acid. Part of the fatty acid of the substitute must therefore be contained in it in the form of a sulphonic acid produced by some oxidising influence upon the chloride of sulphur. The free fatty acids obtained from the substitute absorb more iodine than the latter, owing no doubt to the chlorine in them being eliminated on saponification. From the analyses tabulated above, it is evident that the substitutes A and B have been prepared from the same oil, whereas C must have been obtained from a different oil. On the action of chloride of sulphur ( $S_2Cl_2$ ) on oils very little is known. On adding chloride of sulphur to a fatty oil a homogeneous mixture is obtained, and very quickly an energetic reaction accompanied by evolution of heat, vapours of chloride of sulphur and also a little hydrochloric and sulphurous acids, takes place. After a few minutes the mixture congeals to a solid yellow and rather elastic mass which can easily be crushed in a mortar. On exposure to the air, any excess of chloride of sulphur which may be present, evaporates, and a neutral substance is obtained equal in every respect to the commercial substitute. If too little chloride of sulphur be used the product of the reaction is more or less sticky. The following proportions of chloride of sulphur and oil were found to give satisfactory results:—

100 parts of linseed oil	with 30 parts of $S_2Cl_2$ .
" poppy seed oil ..	35 "
" colza oil ..	25 "
" cotton seed oil ..	45 "
" olive oil ..	25 "
" castor oil ..	20 "

There is evidently no relation-ship between the drying power of an oil and the proportion of chloride of sulphur it requires to form a solid substitute. The analysis of substitutes prepared from various oils and using the above mentioned proportions of chloride of sulphur, in no case led to figures similar to those obtained with substitutes A and B, but the substitute prepared from colza oil appear to be identical with substitute C. Oxidised or "blown" oils require less chloride of sulphur for conversion into solid substitute than the natural oils, the amount of chloride of sulphur decreasing with the degree of oxidation of these oils, and it was found that the "soluble castor oil" of commerce, which is really blown cotton-seed oil, by treatment with about 20 per cent. of chloride of sulphur yields substitutes, the analysis of which exhibits almost the same numbers as that of the substitutes A and B. Considering that chloride of sulphur is more expensive than any of the oils available for the manufacture of india-rubber substitute, the preparation of these compounds from oxidised oils offers a distinct economic advantage. About the constitution of these substitutes no definite opinion can be formed yet, but there is little doubt that they are addition-products of the oil and chloride of sulphur, since they contain chlorine and sulphur in the same proportions as this compound. Separation of glycerol does not take place during the formation of the substitutes, or they would become easily soluble in caustic alkalis, which is not the case. It was

further proved that in saponifying the substitutes with alcoholic potash, glycerol always forms one of the products of the saponification. The fact that the iodine absorption of these substitutes is always very much lower than that of the essential oils, shows that the action of the chloride of sulphur upon the oils consists in the conversion of the unsaturated fatty acids of these oils into saturated compounds. In removing the chlorine from the substitute by treatment with alcoholic potash, unsaturated fatty acids are re-formed, as is proved by the high iodine absorption of the fatty acids so obtained, compared with the low iodine absorption of the corresponding substitute. It is, therefore, highly probable that on saponifying the substitute, the chlorine attached to one carbon atom is separated, together with hydrogen, from the next carbon atom, as hydrochloric acid, and with re-formation of double bonded linking between these two carbon atoms. The other possibility, that simply substitution of hydroxyl for chlorine takes place, is very improbable. Indeed, on employing Benedikt's acetyl-test it was found that no such reaction takes place.

"Brown or black substitute," which is obtained by boiling oils with sulphur, contains only minute quantities of chlorine. Also these substitutes are easily saponifiable with alcoholic potash and on precipitating the sulphuretted fatty acids appreciable quantities of sulphuretted hydrogen are evolved, and the proportion of sulphur contained in the free fatty acids is several parts per cent. lower than that of the original substitute. The iodine absorption of these substitutes and of their fatty acids are very high, so that it would appear that these oils are prepared by boiling linseed oil, or mixtures of linseed and colza oil, with sulphur.—C. O. W.

#### *Contributions to the Analysis of India-Rubber Substitutes.*

R. Henriques. Chem. Zeit. 1893, 17, 916.

In a former paper (see preceding abstract) it had been shown that oxidised oils require less chloride of sulphur for conversion into solid rubber substitutes than fresh oils, and, further, that from the iodine absorption of these substitutes and of their fatty acids, the nature of the oils used for their manufacture could be inferred. Glycerides of the saturated fatty acids being indifferent to chloride of sulphur, mixtures of such fats and of the ordinary oils would yield substitutes with comparatively small quantities of chloride of sulphur, and these would give analytical results very similar to those of substitutes prepared from oxidised cotton-seed oil. Boiling alcohol would, however, easily extract from such compound substitutes all the saturated fats, while the substitutes prepared from homogeneous oils yield nothing to alcohol. Possibly saturated and unsaturated glycerides can be separated by treatment with chloride of sulphur, and subsequent extraction with alcohol.—C. O. W.

#### PATENT.

*Manufacture of Artificial Caoutchouc.* A. F. St. George, Redhill, Surrey. Eng. Pat. 15,544, August 30, 1892.

SUBSTITUTE of turpentine is passed upwards through a heated tube of  $\frac{1}{8}$ th inch or less diameter; the issuing vapour is directed against a spray of hydrochloric acid or other acid, "which has the effect of throwing down solid fragments of caoutchouc." These fragments are thoroughly washed, when they are available for all the purposes to which cleansed, masticated caoutchouc is applicable. The vapour issuing from the tube may be condensed by cooling, and the resulting liquid agitated with hydrochloric acid, when the caoutchouc fragments will be produced.—A. G. B.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*The Action of Salt on the Putrefying Bacteria of Hides.*  
F. H. Haenlein. Dingl. Polyt. J. 1893, 288, 211—215.

Nor only is it considered unnecessary to remove the salt from salted hides before they are put in the soaks to soften, but even advantageous to add salt to the soaks in which dried hides are being softened. The slight loss of hide substance caused by the action of the salt is compensated for by the checked putrefaction and by the softening action of the salt.

Strips of ox hide, prepared as for tanning, were immersed in sterilised water, and in 2 per cent., 10 per cent., and saturated salt solutions respectively, the vessels being left open to the air. After a week, 0.1 cc. of the saturated and 10 per cent. salt solutions developed only one colony on a Koch's plate, whilst the same quantity of the 2 per cent. solution gave 871 colonies, most of which were micrococci, and did not liquefy the gelatin; the same quantity of the water soak gave innumerable colonies, some of which were micrococci, and others liquefying bacilli.

In a second similar series of experiments the beakers were covered with clock-glasses, made tight with filter paper saturated with mercuric chloride. After eight weeks the saturated and 10 per cent. salt solution produced no colonies; the 2 per cent. solution produced many colonies, but no liquefying bacteria; the water soak produced many colonies, including liquefying bacteria. The hide which had been in the water and in the 2 per cent. salt solution was considerably putrefied, soft, and discoloured; whilst that in the other solutions was still fresh and somewhat harder in the saturated solution than in the 10 per cent. solution.

It was noted that the alkaline reaction of the 2 per cent. salt solution was always stronger than that of the water, so that it would seem that this small quantity of salt considerably alters the character of the fermentation, but whether *per se* or by extinction of the liquefying bacteria remains unsettled.—A. G. B.

*The Course of the Absorption of Tannin in the Layers.*  
C. Sadlon. Dingl. polyt. J. 1893, 288, 256. (Compare this Journal, 1893, 273, 610.)

THE absorption of tannin by the hides in the layers is not in simple proportion to the time of laying away, but is constantly diminishing when no addition of tannin is made. A graphic representation of the absorption gives a parabola. Thus it is unprofitable to leave the hides in a layer beyond a certain lapse of time, for after this the loss of interest is greater than the gain in the weight and quality of the leather.—A. G. B.

*Decomposition of Hides during the Process of Tanning.*  
Von Schroeder and J. Pässler. Dingl. Polyt. J. 1893, 289, 137—141, 210—212, 229—234. Compare this Journal, 1893, 297, 610.

AN investigation, undertaken for the purpose of determining whether hides decompose during the process of tanning, was made by Muntz about the year 1877. His method was essentially that now adopted by the authors, and yielded him results which indicated a loss of 8.6 per cent. of hide substance. This conclusion is untrustworthy because of the small size of the pieces of hide with which Muntz experimented.

The authors have studied the question both for dressing hides (uppers) and for sole-leather. In the first series of experiments 32 dried Buenos Ayres horse hides were put into the soaks for seven days, during which time they were once transferred to the tumblers for 20 minutes and returned to fresh water in the soaks. Six days in arsenical limes followed, after which the hides were unhaird, washed, and given a further six days in pure limes. The fleshed hides were soaked for two days, and bated with pigeons' dung at 25° C. for one day, this bating being followed by tumbling in running water, slicking, trimming, and a further few

minutes tumbling in water. After a final tumbling in water and draining on the horse, the hides were ready for the suspenders.

One of the 32 hides was now cut in half, care being taken that no water was expressed during the cutting, and the halves weighed; the one, weighing 5,110 grms., was tanned with the rest of the batch, whilst the other, weighing 5,170 grms., was retained for analysis.

The hides, including the experimental half, were next placed in the first colouring pit, where the liquor was from pine bark and of about 0.60 B. After frequent handling during the first day, the strength of the liquor was increased to 0.80—0.85 B. Six days later the hides were transferred to the second colouring pit, where the liquor had twice the strength. Here they remained for six days, and were then passed to the third and fourth pits, in each of which a similar period was allowed. The last colour contained quebracho, extracted hot, in addition to the pine, and had a specific gravity of 1.50—1.60 B.

Ten weeks in layers with pine and quebracho liquor at 2 B., completed the tannage. The experimental half hide was then air-dried.

For the analyses, representative strips were cut both from the untanned and tanned half, the portions chosen being the butt (*spiegel*), the middle of the back, and the belly and shoulder. The analytical data were obtained for a piece of each portion, and computed for the whole portions and the whole hide. In the following the figures for the whole hide will alone be given, inasmuch as attention has already been drawn to the slight differences which exist in the composition of different portions of the same hide (this Journal, 1893, 610).

The composition of the untanned half was—

	Per Cent.
Air-dried hide substance.....	26.78
Absolutely dry hide substance.....	22.17

The composition of the anhydrous hide substance was—

	Per Cent.
Fat.....	1.10
Ash.....	1.73
Hide substance.....	97.17
	100.00

Nitrogen.....	17.20
---------------	-------

In the fat- and ash-free hide substance the percentage of nitrogen was 17.78.

The tanned half contained—

	Per Cent.
Air-dried leather.....	67.61
Anhydrous leather.....	38.33

The nitrogen in the anhydrous leather was 10.14 per cent., or 10.18 per cent. in the leather extracted with carbon bisulphide and water.

Assuming that the nitrogen in the anhydrous leather corresponds with the same proportion of hide substance as does the nitrogen in the anhydrous, ash-, and fat-free hide substance, the following may be deduced from the above figures:—

	Hide substance,	Nitrogen,
In 100 parts of hide.....	21.54	3.84
In the leather obtained from this quantity of hide,	21.90	3.89
Difference.....	+0.36	+0.05

It is thus apparent that during the tanning of a horse hide, in the manner described above, there is no appreciable loss, or decomposition of hide substance.

In the following table the proximate composition of the anhydrous leather, of the anhydrous hide, and of the leather obtained therefrom, are shown; the last column gives the gain or loss of the several constituents when the

hide passes into leather—the yield of leather from 100 of hide being 172·9 :—

	Anhydrous Leather.	In 100 Parts of Anhydrous Hide.	In 172·9 Parts of Anhydrous Leather.	Loss or Gain.
	Per Cent.			
Fat.....	0·83	1·10	1·44	+ 0·34
Ash.....	0·45	1·73	0·78	- 0·95
Water extract :—				
Tannins.....	3·57	..	6·17	+ 6·17
Not tannins.....	1·49	..	2·58	+ 2·58
Fat-free hide substance.	..	97·17	98·79	+ 1·62
Tannin in pure leather substance.	..	..	63·14	+63·14
Nitrogen.....	10·16	17·29	17·57	+ 0·28
Sugar, calculated as glucose.	0·11	..	0·19	+ 0·19

It will be noted that there is a decrease of ash; this is attributable to the solution in the tanning liquor of a portion of the lime absorbed by the hide during the unhairing. The slight gain of "fat" is possibly due to the acquisition of some resinous substance from the liquors. The figures show that the total tannin absorbed by 98·79 parts of hide substance is 63·14 + 6·17, or 70·3 per cent., so that the hide is not tanned to saturation, for the authors have already shown (*loc. cit.*) that the maximum absorption of tannin is 100 per cent. The figures given in the paper for the different parts of the hide indicate that the flank is less fully tanned than the other parts, probably because of its greater thickness.

A second series of experiments was conducted on exactly the same lines, with calf skins, the preparation and tannage being as follows:—Seven days in the soaks, with several turnings and renewals of water; seven days in old and fresh limes; unhairing; two days in fresh lime. After being fleshed the skins were bated for a day in pigeon dung, whence they were passed into water at 20° C, and, on the same day, were drained and weighed. They were then passed through five colouring pits, the first two of which consisted of pine and the last three of pine and oak; the specific gravity was gradually increased from 0·99° B. to 1·20° B., and the whole colouring process lasted for 28 days. The skins were finally transferred to the layers, where oak and pine liquor at 1·50° B. was used; here they remained for 44 days. After being in the second colouring pit the skins were slicked on the flesh and trimmed; the portions removed amounted to 4·52 per cent. of the raw weight.

As in the previous series of experiments, three skins were divided before the whole batch went into the colours; three halves were tanned with the rest of the skins, whilst the other three halves served to supply analytical data for the raw skins. It was, of course, necessary to analyse the fleshings and trimmings, referred to above, separately, and to correct the analyses for these.

The untanned skin contained 19·06 per cent. of anhydrous material, which gave the following figures :—

	Per Cent.
Fat.....	0·75
Ash.....	1·11
Hide substance.....	98·14
	100·00
Nitrogen.....	17·45

Thus the true hide substance contained 17·79 per cent. of nitrogen.

The anhydrous fleshings and trimmings, which, it will be remembered, had been slightly tanned in the colours, amounted to 1·23 per cent. of the untanned skins and contained—

	Per Cent.
Fat.....	1·72
Ash.....	1·35
Matter soluble in water :—	
Tannin.....	1·93
Not tannin.....	2·81
True leather.....	92·19
	100·00
Nitrogen.....	12·22

The anhydrous leather amounted to 31·82 per cent. of the untanned skins, and contained 9·67 per cent. of nitrogen.

From the above figures it may be calculated that—

	Nitrogen.	Hide Substance.
100 parts of untanned skin contained.....	3·33	18·71
The leather, fleshings, and trimmings from this contained.....	3·23	18·16
Difference .. .. .	- 0·10	- 0·55

It will be seen that a slight loss is recorded in this balance sheet, whereas in that audited for the horse-hide leather there was a slight gain. It is justifiable to attribute such small differences to experimental errors, and to conclude that in the usual practice of tanning hides for dressing leather, there is no appreciable loss of hide substance.

The following analyses show the difference in composition between calf skin and the leather therefrom; the columns are to be interpreted as follows :—

- Percentage composition of calf leather.
- Percentage composition of dried calf skin.
- Composition of the 6·45 parts of dry fleshings and trimmings from 100 parts of dried skin.
- Composition of the 166·95 parts of dry leather from 100 parts of dried skin.
- Total of C. and D.
- Increase or decrease of E over B.

	A.	B.	C.	D.	E.	F.
Fat.....	0·50	0·75	0·11	0·83	0·94	+ 0·19
Ash.....	0·65	1·11	0·09	1·09	1·18	+ 0·07
Water-soluble :—						
Tannin.....	4·17	..	0·12	6·96	7·08	+ 7·08
Not tannin.....	2·00	..	0·18	3·34	3·52	+ 3·52
Fat- and ash-free hide substance.....	..	98·14	4·43	90·74	95·17	- 2·97
Tannin in the pure leather.....	..	..	1·52	63·90	65·51	+65·51
Nitrogen.....	9·67	17·47	0·79	16·15	16·94	- 0·53
Sugar (as glucose).....	0·18	..	..	0·30	0·30	+ 0·30

On comparison of this table with the similar table given above for horse leather, it will be noted that there is a slight gain of ash in the calf leather, whereas there was a loss in the horse leather; this difference the authors attribute to the more drastic bating and washing which the calf skins receive; these remove the lime more completely than it is removed from the horse hides before tanning. The loss of hide substance is of course magnified by calculation on the dry skin and leather; several unimportant suggestions are made to account for the loss, otherwise than as a decomposition of hide substance.

One hundred parts of the hide substance of calf skin absorbed 78.2 parts of tannin, of which 7.7 parts are easily removed by water.

The third series of experiments is concerned with sole leather. The dry Buenos Ayres hides were put into fresh water soaks, where they remained for nine days with several changes of water. They were then drained and sweated for three days. Unhairing, washing, fleshing, and another washing completed the preparation. The division of the experimental hides was then made.

The hides passed through four suspenders, in which they remained two, three, four, and five days respectively. The suspender liquor was prepared from a sour bark from old layers; it consisted of the extract from this bark diluted with 3, 1,  $\frac{1}{2}$ , and 0 times its volume of water for each of the four suspenders respectively. The extract had a specific gravity of 1.0059 (0.86° B.) and contained—

	Grms. in 100 cc.
Tannin .....	0.226
Not tannin .....	0.916
Total acid (as acetic acid) .....	0.493
Volatile acids .....	0.300
Non-volatile acids .....	0.193

The fifth and final suspender contained 30 kilos. of pine bark for the 7 $\frac{1}{2}$  hides, and was followed by a pit containing 40 kilos. of oak bark and 30 kilos. of pine bark, in which the hides remained for seven days. The first layer contained liquor from 66 kilos. of oak- and 147 kilos. of pine-bark, and the second contained liquor from 100 kilos. of oak-bark, 60 kilos. of pine-bark, and 20 kilos. of valonia; the tanning lasted for 37 weeks and six days.

The experimental hides were divided into butt, shoulders, and belly; representative portions of these were analysed and the composition of the whole portions and of the whole hide computed. The hide contained 28.84 per cent. of dry substance, which was composed of—

	Per cent.
Fat .....	0.28
Ash .....	0.30
Hide substance .....	99.42
	100.00

The nitrogen in the dry hide was 17.76 per cent., or 17.87 per cent. in the ash- and fat-free hide. 100 parts of undried hide gave 52.45 parts of absolutely dry leather, which contained 9.40 per cent. of nitrogen.

Thus a balance sheet may be made out as follows:—

	Hide Substance, Nitrogen.	
In 100 parts of ash- and fat-free hide .....	28.67	5.12
In the leather therefrom .....	27.50	4.93
Difference .....	1.08	0.19

Calculated on the dry hide substance, the loss during tanning becomes 3.77 per cent. The authors, whilst fully aware of the sources of error introduced by the difficulty of determining the moisture in the hide and leather, feel compelled to admit that this is a genuine loss; they attribute its magnitude to the length and severity of the process of tanning sole leather. At the same time the loss is much smaller than was stated by Muntz (see above), and in practice

should not exceed the percentage which the authors have found. A comparison of the three series of experiments may be made:—

	Percentage Loss or Gain of Anhydrous Hide Substance.	Duration of Tanning.
(1.) Horse leather.	+1.67	100
(2.) Calf leather.	-3.04	77
(3.) Sole leather.	-3.77	320

The authors again advert upon the German custom of estimating the yield of leather by the increase in weight of the water-containing hide (compare this Journal, 1893, 610). The butt in this condition always contains the least water, so that it will appear to be the best tanned; as a fact the bellies are always more tanned than the shoulders, and these more than the butts.

The following table shows the composition of sole leather, and the increase or decrease of its constituents over those of the hide. 100 parts of anhydrous hide yield 181.87 parts of anhydrous leather.

	Leather.	Anhydrous Hide Substance.	In 181.87 Parts of Anhydrous Leather.	Loss or Gain.
	Per Cent.	Per Cent.		
Fat .....	0.25	0.28	0.45	+ 0.17
Ash .....	0.37	0.30	1.58	+ 1.28
Water-soluble:—				
Tannin .....	4.73	..	8.60	+ 8.60
Not tannin .....	4.25	..	7.73	+ 7.73
Fat- and ash-free hide substance.	..	99.42	95.65	- 3.77
Tannin in pure leather.	..	..	67.86	+ 67.86
Nitrogen .....	9.40	17.76	17.10	- 0.66
Sugar (as glucose) ..	0.36	..	0.65	+ 0.65

It will be seen that 100 parts of ash and fat free hide substance have absorbed 76.91 parts of tannin.—A. G. B.

## PATENTS.

*Improvements in the Treatment of Leather.* H. Lebl and E. Atlas, Vienna. Eng. Pat. 1216, January 19, 1893.

THE claims in this patent are for producing velvet-leather, having a fine and short nap or down, from ordinary leather by roughening on the grain side, and for smoothing such velvet-leather, where desired, by ironing and pressing. Heretofore velvet-leather has always been produced by roughening the flesh side, which, however, is too coarse for a fine nap. The process of roughening is purely a mechanical one, being performed by friction with some gritty material or by a sand blast.—A. G. B.

*An Improved Process for treating and purifying Sod and other Oils, and Apparatus therefor.* F. N. Turney. Nottingham. Eng. Pat. 1349, January 21, 1893.

See under X11., page 46.

*Improvements relating to the Treatment of Hides and Skins.* H. H. Lake, London. From A. J. Strauss, Paris. Eng. Pat. 2545, February 4, 1893.

THIS invention relates to a process of transforming tanned goat, sheep, calf, and other hides into tawed hides so as to combine the suppleness and other qualities imparted to the hides by tawing, with the strength obtained by tanning.

The tanned goat-skins (one dozen) are submitted to the following operations:—

- (1.) Working in a tumbler with tepid water.
- (2.) Working in a tumbler with a solution of 30 grms. of potash in 60 litres of water for half an hour.
- (3.) Soaking for five minutes in a very weak solution of hydrochloric acid, which has the effect of neutralising the potash.

These three operations constitute the cleansing of the hides "from injurious tanning materials."

- (4.) Pounding and working for 2—3 hours in a tepid bath composed of—

Solution of quebracho (30 "litres" of pulverised quebracho to 150 litres of water).....	15 litres.
Glycerin.....	0.15 ..
Wheat flour.....	75 grms.
Brum.....	30 ..
Alum.....	19 ..
Water.....	30 litres.

- (5.) Two hides are placed flesh to flesh on a marble table and rubbed with an ordinary tanner's grit-stone.

- (6.) The hides thus arranged are rubbed on both sides and brushed with a solution of 100 grms. of ammonia in 15 litres of water.

- (7.) They are then impregnated with a solution of campeachy wood, prepared by boiling 16 kilos. of the wood in 110 litres of water. The hides, still together, are immersed in this liquor, and are then spread on tables to "oxidise the solution of campeachy," the treatment being repeated until a deep chestnut colour has been attained.

- (8.) The hides, still together, are next brushed, on a curved table, with a solution of sulphate of iron and sulphate of copper in the proportion of 60 grms. to 15 litres of water.

- (9.) The hides are then again immersed in a campeachy bath (8 litres of campeachy extract to 100 litres of water), and afterwards separated and rinsed in pure water.

- (10.) Each hide is finally aired, placed on a table, and rubbed on the hair side with a round-edged tool.

The final operations, which are known in tawing, need not be described.—A. G. B.

*An Improved Fat Emulsion and method of producing the same.* M. Ekenberg, Stockholm, Sweden, Eng. Pat. 17,566, September 18, 1893.

See under XII., page 16.

## XVI.—SUGAR, STARCH, GUM, Etc.

*The Composition of Lime-tree Honey.* M. Maquenne, Comptes rend. 117, 127—129.

In dry seasons the leaves of the lime-tree often become covered with a saccharine exudation, known in France as *Miellée* or *Miellat*, on account of its taste. Sometimes this is sufficiently abundant to drop off; apparently its formation is connected with the presence on the leaves of a parasitic insect. Obviously its origin is closely akin to that of various kinds of manna. From polarimetric observations and determinations of the copper reducing power of the saccharine matter before and after hydrolysis, Boussingault concluded in 1869 that ordinary sugar was mainly present, along with invert sugar, and a little dextrin. The author finds that *melezitose* is present in large quantity; by washing the leaves with water and evaporating the solution 100 kilos. of leaves furnished about 1 kilo. of brown syrup of strongly sweet taste, with slightly bitter after taste.

Alcohol precipitated a gummy matter, after removal of which crystals gradually formed, from which ultimately 100 gm. of pure *melezitose* were obtained. The syrup contained something like half its weight of solid matter, so that the *melezitose* probably amounted in all to about 40 per cent. of the total solid matter. Glucose constitutes a large fraction of the remainder; a gummy substance, partially precipitable by alcohol, was also present. Hence lime-tree *Miellée* has a composition closely akin to that of larch manna and the manna of *Alhagi camelorum*.—C. R. A. W.

*The Carbohydrates of the Jerusalem Artichoke.* C. Tauret, Comptes rend. 117, 50—53.

THE juice is treated with lead acetate and the excess of lead eliminated; warm concentrated baryta water is then added in large quantity, whereby a precipitate is formed rich in inulinic matters; additions of alcohol of gradually increasing strength throw down further precipitates. By methodically treating these fractionally with carbonic acid and alcohol, and again fractionally precipitating with baryta and alcohol, dextro-rotatory saccharose, and various levo-rotatory carbohydrates are finally obtained. A litre of juice contains a total of about 160 grms. of saccharose, inulin, pseudo-inulin, inulinin, helianthenin, and synanthrin; the latter two are new products, and are separated from the others by taking advantage of their varying solubilities in alcohol of different strengths. All the constituents named suffer hydrolysis under the influence of acids, or even water, yielding a mixture of levulose and glucose. Helianthenin crystallises in microscopic needles, melting at 176°; its rotatory power is  $\alpha_D^{20} = -23.5^\circ$ . In water it is very soluble, less so in weak alcohol, the less the greater the alcoholic strength; it is fermentable with beer-yeast, but only with difficulty. The author represents its composition (after drying at 110°) as  $12(C_6H_{10}O_5)_3H_2O$ , or preferably  $C_{72}H_{120}O_{72}$ . Synanthrin is amorphous, and represented by the formula  $8(C_6H_{10}O_5)_2H_2O$ , or preferably  $C_{96}H_{160}O_{96}$ ; it melts at 170°, and has the rotatory power  $\alpha_D^{20} = -17^\circ$ . Weak acids hydrolyse both, forming mixtures of glucose and levulose.—C. R. A. W.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Chemistry of Hops.* C. J. Lintner and A. Bungener, Zeits. ges. Brauw. 1893, 357.

According to the authors, the crystals obtained from Haiduck's  $\alpha$ -resin are different from H. Bungener's bitter acid from hops, but appear to be identical with the bitter principle obtained by Lerner.—A. K. M.

*Influence of Acidity in Worts on the Composition of "Low-Wines."* L. Lindet, Comptes rend. 117, 122—125.

It is a common practice with distillers to acidulate worts with a mineral acid before fermentation, with the object of preventing the development of certain undesirable organisms; more alcohol is thus formed, since the production of lactic and butyric acids is diminished. In certain cases, however, the formation of these organic acids is desired; mineral acids (such as sulphuric, hydrochloric, and hydrofluoric acids) are then not added; under these circumstances a wort, practically neutral before yeasting, gradually becomes acid to an extent exceeding 3 grms. per litre, expressed as sulphuric acid.

The author finds that the addition of mineral acids also diminishes the proportion of bases, volatile acids, and compound ethers formed during fermentation, but increases the quantity of higher alcohols developed, this being the general

result in a number of carefully made duplicate experiments where a given wort (from maize, barley, &c.) was divided into two portions, each treated absolutely alike throughout, excepting that in one case a small percentage (e.g., 1.5 gram. per litre) of sulphuric or hydrofluoric acid was added, and in the other not. In a manufacturing experiment with 3,000 kilos. of potatoes, one half fermented in the presence of hydrofluoric acid, and the other half without mineral acid, the following comparative figures were obtained on systematic fractional distillation of the "low-wines" produced by the first distillation of the wash:—

	Acidulated with Hydrofluoric Acid.	Not Treated with Acid.
	Per Litre of Alcohol. Cc.	Per Litre of Alcohol. Cc.
Higher alcohols insoluble in water	2.05	1.65
Amylic alcohol contained therein.	1.43 Gm.	1.00 Gm.
Bases.....	0.107	0.127
Volatile acids (calculated as acetic acid).	0.78	1.37
Compound ethers (calculated as acetic ether).	0.43	1.47

—C. R. A. W.

*The Estimation of the Ready-formed Sugars in Malt.*  
J. Jais. Zeit. für das gesau. Brauw. 16, 1893, 357—360 and 365—367.

THE author finds that in the extraction of the malt by alcohol, in the ordinary method of determining the above, the acid of the malt is without augmentative influence on the amount of the substances reducing Fehling's solution. The amount of extract obtained from a malt is of course conversely as the strength of alcohol employed, and this, the author shows, is due to diastatic action taking place on the already existing starch products in the presence of the weaker alcohols, and not to greater solubility of the sugars in them; for, on extracting a malt with boiling alcohol (94.4 per cent.), and at the same time killing the diastase and then extracting with water, the total amount of sugars contained in the two extracts is equal to that obtained by digesting a malt of ordinary diastatic activity for 15 minutes with cold water. In the case, however, of low-dried and green malts even this short extraction with water was sufficient to bring about a considerable degradation, and hence an increase on the amount of sugars obtained by the preceding method.

The author recommends the following method for estimating the ready-formed sugars in any kind of malt:—10 grms. of the malt are digested with 500 cc. 94 per cent. alcohol for 1—2 hours, in a boiling water-bath, in a flask fitted with an inverted condenser. The alcoholic solution is filtered off when cold and the residue washed with alcohol, dried at 60° C., and extracted with water at 55° for a considerable time, with constant shaking. The sugars are then estimated in the two extracts. Ether cannot be used to separate the fat from the alcoholic extract, as it dissolves an appreciable amount of cane-sugar. By extracting the residue, after evaporating off the alcohol *in vacuo*, with hot water, and filtering the solution when cold, the greater part of the fat was left on the filter. A blank experiment performed with soluble starch proved that no diastatic action takes place under these conditions. The enpic reduction of the extracts was calculated as invert-sugar, the increase on digestion with  $\frac{1}{4}$ th normal hydrochloric acid (Meissl's method) as cane-sugar, while the further increase on inversion according to Sachsse's method was calculated as gum.

The alcoholic extract contained the greater part of the cane-sugar and but very little gum, of which latter the aqueous extract contained a large amount. The total amount of cane-sugar found in the two extracts corresponded to that found in a hot-water mash of the same malt. The

cane-sugar contained in these extracts cannot be estimated by the polariscope owing to the levo-rotatory action of the gum they contain.—J. G. W.

*The Degradation of Starch by the Action of Diastase.*  
C. J. Lintner and G. Dull. Ber. 26, 16, 2533—2547.

THE authors find that five products only are the result of the action of diastase upon starch, viz., three dextrans, which they term amylo-, erythro-, and achroo-dextrin, and two sugars, isomaltose and maltose, so that, according to them, Brown and Morris's hypothesis regarding the transformation of starch is no longer tenable, their so-called amyloins consisting partly of mixtures of dextrin and isomaltose and being partly identical with them (this Journal, 1893, 851—855).

Their process of degradation was conducted as follows:—100 parts of potato starch were mashed with 500 parts of water at a temperature of 70° C., with the addition of air-dried malt in varying amount up to the extent of 6 parts, according to the dextrin it was desired to obtain. The dextrins and sugars were isolated by stopping the diastatic action at the necessary point by boiling and then repeatedly fractionating the product with alcohol.

*Amylodextrin* ( $C_{12}H_{20}O_{10}$ )<sub>54</sub>, was obtained by stopping the degradation while iodine still gave a blue reaction and then saturating with hot 10 per cent. alcohol. The dextrin separated out on cooling, and, after purification by repeated fractionation with 40—50 per cent. alcohol, was obtained as an extremely light, white powder, only slightly soluble in cold water, but readily so in hot. It did not reduce Fehling's solution, gave a deep blue colour with iodine, and had a specific rotary power  $[\alpha]_D = 196^\circ$ . Its molecular weight, determined by Raoult's method, corresponded to the above formula.

*Erythrodextrin* ( $C_{12}H_{20}O_{10}$ )<sub>17</sub>.  $C_{12}H_{22}O_{11}$ , was prepared by stopping the diastatic action when iodine gave a reddish-brown colouration, saturating with hot alcohol and filtering. The filtrate was concentrated to a syrup and repeatedly treated with 70 per cent. hot alcohol to remove the sugars. It is easily soluble in water, but scarcely so in 50 per cent. alcohol. Its reducing power is 1 per cent. that of maltose and its  $[\alpha]_D = 196^\circ$ . With iodine it gives a reddish-brown colouration.

*Achroodextrin* ( $C_{12}H_{20}O_{10}$ )<sub>5</sub>.  $C_{12}H_{22}O_{11}$ , was obtained by stopping the degradation when iodine ceased to give a colouration, and evaporating the product to a syrup, which was then treated a few times with 60—70 per cent. alcohol to remove traces of erythrodextrin. The remainder was evaporated to a syrup and the sugars extracted by treating successively with 90, 85, and 80 per cent. alcohol. It is very readily soluble in water, but is scarcely so in 70 per cent. alcohol. Its reducing power is 10 per cent. that of maltose, its  $[\alpha]_D = 192^\circ$ , and it gives no reaction with iodine solution.

*Isomaltose*,  $C_{12}H_{22}O_{11}$  (probably  $C_{12}H_{22}O_{11} + H_2O$ ), was isolated by stopping diastatic action when a red iodine reaction was obtained. The crude syrup was fractionated with 85—90 per cent. alcohol, all fractions having  $[\alpha]_D = 140^\circ$  being collected, concentrated, dissolved in hot methyl alcohol and precipitated with absolute ethyl alcohol. All fractions having  $[\alpha]_D = 140^\circ$  were again united and the operation repeated until no trace of maltose could be detected in the resulting body by means of the osazone. Isomaltose has not yet been obtained in a crystalline form, but the authors are in hopes of doing so from methyl alcohol solutions. It is extremely soluble in water, in 80 per cent. alcohol, and still more so in methyl alcohol, but in hot 95 per cent. ethyl alcohol it is scarcely soluble. It readily caramelises on exposure to heat and has an intensely sweet taste. Its reducing power is 80 per cent. that of maltose, and its  $[\alpha]_D = 140^\circ$ . It is fermented by yeast with greater difficulty than is maltose, into which it is converted by the action of diastase. Its osazone crystallises from water in spherical aggregates of extremely fine yolk-coloured needles, which soften at 138—140° C. and melt at 150—153° C. It is much more readily soluble in

water and alcohol than is maltosazone, from which it is also easily distinguished by its melting-point and its crystalline form.

The numbers obtained with isomaltose by Raoult's method point to its formula as being  $C_{12}H_{22}O_{11} + H_2O$ .

The authors propound the following theory of starch-transformation. Starch is a union of high molecular complexes and under the action of diastase, dilute acids, or combined heat and pressure, splits up into its high molecular components, of which amyloextrin is the first to be liberated. Amyloextrin is hydrolysed into three molecules of erythroextrin, and the latter again into three of achroodextrin, from which by further hydrolysis isomaltose results, which is then converted into its isomer maltose.

These stages are represented by the following equations:—

These stages, however, proceed simultaneously.

The authors attempt to explain the stoppage of the degradatory process which takes place under restrictive conditions, as for instance, at a temperature of  $70^\circ C.$ , by the supposition that in the conversion of erythroextrin into achroodextrin under unfavourable circumstances part only of the resulting achroodextrin is further degradable, the remainder "taking a form which withstands diastatic action." Under the same conditions the conversion of isomaltose into maltose is restricted.—J. G. W.

#### *The Preparation of Betaine and Choline from Malt-Combs and Wheat Germs.* E. Schulze and S. Frankfurt. Ber. 26, 1893, 2151—2155.

BETAINE and choline can be obtained from the above in the following manner:—The material is extracted with water, lead acetate added so long as a precipitate is produced, the solution acidified with sulphuric acid and repeatedly filtered. Phospho-tungstic acid is then added and the resulting precipitate washed and treated in the cold with milk of lime. The filtrate from the insoluble calcium compounds is treated with carbonic anhydride to remove the excess of lime, filtered, neutralised with hydrochloric acid, evaporated to a syrup and the latter extracted with hot 90—95 per cent. alcohol. Alcoholic mercuric chloride solution is added to the extract which is then allowed to stand for several days, at the end of which the separated mercuric double salt is removed and crystallised from water. The portion of the salt difficult of solubility, contains the betaine while the easily soluble part consists of the choline compound. They can be separated from each other by repeated fractional crystallisation from water, or, by decomposing with sulphuretted hydrogen and treating the hydrochlorides so obtained with cold absolute alcohol. The choline salt dissolves while the betaine compound remains behind.

Three kilos. of wheat embryos yielded 5—6 grms. of betaine hydrochloride, the yield of the choline salt being considerably less. Malt rootlets yielded a somewhat less amount of the betaine salt but a rather larger quantity of the choline compound.—J. G. W.

#### *The Development and Ripening of the Cider Apple.* L. Lindet. Comptes. rend. 1893, 117, 696—698.

THE author has studied the gradual transformation of starch into sugars in the case of the cider apple by making analyses of samples taken from the same tree from July to November

inclusive. The following figures for the extreme terms of the series will illustrate the changes that occur.

	July 24.	November 3.
Average weight of an apple.....	Grm. 21'5 Per Cent. 1'8	Grm. 76'5 Per Cent. 0'8
Starch.....	1'1	2'9
Saccharose.....	0'4	9'4
Invert sugar.....	0'5	0'2
Acidity as malic acid.....	0'4	0'2

He has also examined the ripening of apples that have been picked and allowed to ripen in the dark, and has found that corresponding progressive changes take place.

—B. B.

#### *The presence of Boric Acid in Beer.* J. Brand, Zeits. ges. Brauw. 1893, 16, 197.

A CONSIGNMENT of German export beer had been rejected by the chemist of the custom house of Montevideo on the ground that it contained boric acid. This acid, however, occurs naturally in beer and is derived from the hops, in which it was first observed by Delton. The quantity of boric acid thus present is very small and to judge by the intensity of the turmeric paper test, less than 50 milligrms. per litre. For analysis at least 100 cc. of beer should be employed and examined by Gooch's method. The quantity of boric acid naturally present will turn turmeric paper only faintly red. This stain on moistening with alkalis turns bluish-green, which proves that it is due to boric acid. An addition of 5 milligrms. of boric acid in 100 cc. of beer (an amount which with regard to its antiseptic action, can scarcely be considered) will give by Gooch's method a very intense reddening of turmeric paper.—C. O. W.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

### (A.)—CHEMISTRY OF FOODS.

*Saffron and its Adulterants.* E. Vinassa. Archiv. der Pharm. 1892, 231, 353, and Dingl. Polyt. J. 290, 17.

See under XXIII., page 71.

*Analysis of the Butters of Commerce.* C. Viollette. Comptes. rend. 117, 856—858.

THE author's determinations of the weight *in vacuo* of 1 cc. of genuine butters of various origin, margarines, and mixtures of the two have led him to the belief that by means of a density determination alone commercial butters may be rapidly sorted into three classes; viz., those undoubtedly adulterated with margarine, those doubtful, and those that may be considered practically pure. Mixtures of margarine and butter have uniformly the density due to the constituents without contraction, &c.; at  $100^\circ$  1 cc. weighs (*in vacuo*)—

	Grm.	Grm.
Genuine butter.....	0'86320 to 0'86425	
Margarine.....	0'85790 to 0'85865	

Animals fed chiefly on hay furnish butters of lower density than those from cows allowed grass, cake, and roots, &c. Out of 500 samples, only two (from high fed

beasts) give still higher values, 0.86530 and 0.86540; whilst one, from a cow fed on straw and dry hay, gave a lower figure, 0.86277. Accordingly he has had constructed an extremely delicate areometer by means of which the density at 100° of the substance examined can be at once determined with reference to these three classes, the stem having three corresponding marks upon it. A quantity indicating 0.0001 gram. per cc. represents 1.4 mm. of length on the stem. Conveniently, three smaller areometers may be employed, No. 1 with three marks representing respectively 0.86215, 0.86266, and 0.86320 gram. per cc.; No. 2 and No. 3 arranged for substances of lower density, 0.857 to 0.86266; for these a table is provided giving the proportions of margarine and butter with which the observed density approximately corresponds. Substances yielding figures lower than 0.86266 but higher than 0.86215 (first and second marks on No. 1) may possibly be pure butters, but are more likely to contain margarine; they are therefore considered doubtful, and should be subjected to chemical examination.—C. R. A. W.

*On the Internal Temperature of Bread as it comes from the Oven.* M. Balland. *Comptes rend.* 117, 519–521.

In a previous paper the author advanced the opinion that the internal temperature of bread when taken from the oven is from 97° to 100°, and does not exceed the latter temperature. In his experiments he used loaves of 1 kilo. in weight and the thermometer was inserted in a hole made with a bodkin. The author has since then carried out other experiments, using carefully-graduated thermometers, and inserting them in the bread before baking. The experiments were carried out in the central laboratory of the War Department at the Invalides, and at the military bake-house at Billy.

*Laboratory of the Invalides.*—Here there is a Biabaud oven for 60 kilos. of bread, and it is furnished with a pyrometer.

*1st Experiment.*—With two similar long-shaped loaves A and B, of 750 grms., left in the oven for 40 minutes. The temperature of the oven when the bread was placed in it was 300°, and when the bread was taken out 265°.

A.....	100°·2
B.....	99°·8

*2nd Experiment.*—With two similar loaves of the same weight and shape, A being left in the oven 32 minutes and B one hour. The initial temperature of the oven was 302°, and 275° when A was taken out, and 225° when B was taken out.

A.....	100°·8
B.....	101°·0

*3rd Experiment.*—With two similar loaves of the same weight and shape, A being left in 28 minutes and B one hour. The initial temperature of the oven was 294°, 256° when A was taken out, and 225° when B was taken out.

A.....	101°·0
B.....	101°·0

*4th Experiment.*—With two similar long-shaped loaves of 1,500 grms. A was taken out after 75 minutes and B after 85 minutes.

A.....	99°·2
B.....	100°·6

*5th Experiment.*—With two similar loaves of 2 kilos. left in the oven for 70 minutes.

A.....	100°·8
B.....	100°·8

*6th Experiment.*—With small elongated loaves of from 150 grms. to 200 grms., left in the oven for from 20 to 40 minutes, the temperature was found to be between 100°·5 and 101°·5; on one occasion it reached 105°, but in this case the bulb of the thermometer was partly in the crust.

*7th Experiment.*—With rolls of the same weight it was found in like manner that the temperature only exceeded 101°·5 when the thermometer was inserted in the crust.

*Bake house at Billy.*—The Lamoureux oven used by the author can bake 270 kilos. of bread, and the batches succeed each other continuously, day and night. There is no pyrometer, but the temperature is certainly not less than that of the oven at the Invalides.

1. With the loaves in ordinary use (which join other loaves in four places and weigh 1,500 grms. after 45 minutes baking) the temperature was from 100°·5 to 101°·5.

2. With three similar loaves, baked separately, the temperatures were 102°, 102°, and 103°·6. In the latter case the bulb of the thermometer touched the crust.

3. With a loaf of 750 grms. made with biscuit dough, the thermometer registered 101°.

4. With soldiers' biscuits the results were uncertain, the thermometers being too near the crust.

From these experiments, carried out in different ovens and with loaves of different size and shape, the author concludes that the temperature of the crumb of the bread during baking reaches to 100° or 102°, while that of the crust is much higher. Beyond 100° the aqueous vapour, imprisoned by the crust, is under pressure, and when the pressure is lowered by making a hole in the crust, as in the author's first experiments, the temperature does not exceed 100°.—D. E. J.

## PATENTS.

*Improvements in the Manufacture of Yeast.* F. M. Pelsky, Paris. Eng. Pat. 20,787, November 16, 1892.

A MIXTURE of green barley and wheat-malt flours is kneaded with water and allowed to turn sour. It is then digested at a temperature of 62°–65° C., and cooled. Pressed yeast is then added and the mixture divided into two parts. To one part tartaric acid and subsequently sodium bicarbonate are added, and to the other ammonium carbonate. The two are then mixed and allowed to stand. The resulting product is washed with a solution of calcium phosphate and pressed.—J. G. W.

*Process of curdling Milk and producing Cream and Butter.* M. Julien, sen., and A. Brin, London. Eng. Pat. 22,115, December 2, 1892.

SKIMMED milk and any fatty matter, such as margarin or olive oil, are emulsified by subjecting them, separately or in a state of mixture, under very high pressure (about 250 atmospheres), and in the form of very fine jets ( $\frac{1}{32}$  inch diameter), to violent impact, by projecting the jets either against one another or against a common surface of impact. The apparatus for so doing is the subject of another patent, 14,840, August 2, 1893. Butter is prepared from the curdled milk in the usual manner.—J. G. W.

*Improvements in the Utilisation of Flours which are rich in Diastase.* L. Briant, London, and W. H. Walker, Southport. Eng. Pat. 23,748, December 23, 1892.

SINCE the introduction of high-class flours, bread has become less moist and of less flavour, this being due to the fact that in the milling of flours the germ, which is markedly diastatic, is entirely or almost entirely separated. The present invention consists in the separation of diastase from low-grade unmalted wheaten and other flours, which are now practically rejected for bread-making, and adding the diastase so obtained to higher-class flours during the process of making them into bread.

The process employed for extracting the diastase is as follows:—The flour is extracted with water at a temperature not exceeding 120° F., for 1½ hours, with constant stirring, a small quantity of either sulphurous acid or salicylic acid being added as an antiseptic. The extract is filtered and evaporated without delay *in vacuo* to a specific gravity of about 1.450, at a temperature not exceeding 120° F. The extract is used in bread-making in the proportion of from 6 oz. to 1 lb. per sack of flour.—J. G. W.

*Improvements in Milk-Testers.* M. Pedersen, Dursley. Eng. Pat. 1888, January 27, 1893.

THIS improved milk-tester for the estimation of the quantity of cream by means of centrifugal action, consists of a cylinder, closed at one end and open at the other, into which slides another cylinder, open at the lower end and partially closed at the other by a plug of glass tubing of narrow bore. When filled with milk and placed on the centrifugal disk, with the glass plug towards the centre, the cream rises into the narrow bore of the glass plug, the lower end of which is bevelled to facilitate its so doing. The length of the column of cream is then measured off.

—J. G. W.

*Improvements in the Preservation of Alimentary and other Substances, and Apparatus therefor.* C. A. Sahlstrom, London. Eng. Pat. 1954, January 28, 1893.

THE substance to be preserved is placed in baskets within a special receiver and covered with a preservative solution, the nature of which varies according to the character of the substance to be preserved. The receiver is then exhausted, with the result that all the gases contained in the tissues of the organic substance are removed. The atmospheric pressure is then restored by very slowly admitting air into the receiver, and then a pressure of 2–6 atmospheres applied, in order that the tissues may be properly impregnated with the preservative fluid. This is then run off and the substances packed in common boxes or barrels, with or without preserving fluid.

The following solutions are recommended for the several purposes:—For preserving fish for a few days, a 1–2½ per cent. solution of common salt, or pure sea water. For preserving fish for a longer time, the previous solution, with the addition of 1–2½ per cent. of boracic acid or borax,  $\frac{1}{100}$ – $\frac{1}{50}$  per cent. of glycerin, and  $\frac{1}{1000}$ – $\frac{1}{100}$  per cent. of essence of cloves. For salting or pickling fish or meat, a stronger solution of salt with only a very small proportion of glycerin and boracic acid. For preserving eggs, a smaller percentage of boracic acid and a larger one of glycerin. For preserving fruits, a solution containing 2–5 per cent. of sugar,  $\frac{1}{2}$ –2 per cent. of glycerin, 1–1½ per cent. of boracic acid, and  $\frac{1}{1000}$ – $\frac{1}{100}$  per cent. of essence of cloves. For preserving meat, melted tallow, either alone or mixed with 1–2½ per cent. of boracic acid.

It is claimed that by this method the substances after treatment contain only a trace of the ingredients of the preservative solution, retain almost unaltered their original appearance and taste, and require no special arrangements for conveyance to distant markets.—J. G. W.

*An Improved Extract of Cocoa.* T. R. Allison, London. Eng. Pat. 1117, February 24, 1893.

THE shells only of the fruit of the cocoa plant are macerated with water, with the addition of bran. The whole is then heated to a point just short of boiling for three hours, filtered and concentrated. It is claimed that the addition of bran effects a better extraction of the essential principles of the shells, and obviates the need of skimming off the cocoa fat.—J. G. W.

*Improvements in Centrifugal Separators for Cream and Butter.* A. Wahlén, Bainbridge, U.S.A. Eng. Pat. 11,026, June 6, 1893.

THE milk is received into an auxiliary separating vessel in which any foreign substances are arrested, and, as the milk is thrown over the edge of this vessel by centrifugal action, partial separation of the cream from the watery portions also takes place. The materials pass into the main separating vessel, consisting preferably of a hollow conical vessel having a partially flat bottom, the centre portion of which is upwardly conical, and provided with one or more downward openings, around which externally is a cylindrical lip.

In the preparation of butter, the cream passes downwards through these openings, and, being discharged from the cylindrical lip, is received upon the conical under surface

of the bottom, and is there spread out by centrifugal action in such a thin layer that the watery particles pass off and the buttery globules coalesce; the separated materials being received into an annular chamber below the centrifugal separating vessel.

In the preparation of cream, a moveable receiver below the butter-separator is raised and receives the cream from the annular lip so as to prevent any further separation of the fatty and watery constituents being effected. The cream is discharged by a suitable spout from the intercepting vessel.—J. G. W.

*Improvements in the Manufacture of Dough from Cereals, and Apparatus therefor.* F. J. Gelinck, Riga. Eng. Pat. 15,067, August 5, 1893.

THE corn, after washing and freeing from all impurities, is steeped in water at 50° C. for 1½ hours and then crushed between a pair of rollers. The crushed mass is conducted into a ribbed casing of peculiar shape, in which a conveyer-screw rotates. By means of the screw-thread and the ribs of the casing, the crushed mass is further reduced, any pieces which may have escaped crushing being cut up by rotating knives. The whole is then passed through a perforated plate into another similar compartment in which further reduction takes place, it being finally passed through a plate having smaller perforations, when the dough is ready for use.—J. G. W.

*Method of Purifying Water by Oxide of Tin.* H. von der Linde and C. Hess, Uerdingen-on-the-Rhine, Germany. Eng. Pat. 19,216, October 12, 1893.

THE water to be purified is filtered through materials impregnated with oxide of tin. This substance, it is stated, acts as an extremely energetic oxygen carrier, and effects the rapid oxidation of the organic impurities through the agency of the dissolved oxygen present in the water.

—H. T. P.

## (B.)—SANITARY CHEMISTRY.

### PATENTS.

*Improvements in the Treatment and Utilisation of Sewage, and Plant therefor.* A. O. Jones, Harrogate, Yorks. Eng. Pat. 21,291, November 23, 1892.

A PROCESS of treating sewage so as to obviate the dissemination of offensive odours, and to utilise the solid and liquid constituents as completely as possible. The sewage is filtered in a closed chamber through a filter-bed supported on a raised false bottom. During filtration either cold or hot air is drawn through the apparatus, or the latter itself may be heated, the noxious vapours given off being passed into a destructor furnace to render them harmless. The material of the filter-bed is afterwards employed, in conjunction with the solid portion of the sewage, for the manufacture of artificial fuel, or the production of heating gas, &c., in the manner indicated in two earlier patents (Eng. Pats. 14,253, 1890, and 11,764, 1891; this Journal, 1891, 846, and 1892, 597). In the first case the filtering material may be peat, brick-dust, mould, &c.; in the second, coal-dust, town refuse, soot, &c. The liquid portion of the sewage may be sprayed into the furnace, or it may be refiltered and aerated until sufficiently pure and discharged into a water-course. Another form of apparatus is described in which the liquid portion of the sewage is evaporated by maintaining a partial vacuum in the outer chamber, the vapours given off being conducted to a furnace, &c., whilst the sludge is periodically withdrawn at the bottom of the chamber.—H. T. P.

*Improvements in Apparatus for the Treatment of Sewage Matter.* M. Nadein, B. Ewdokimoff, and S. de Baschmakoff, St. Petersburg, Russia. Eng. Pat. 21,931, November 30, 1892.

THIS is an improvement on a previous invention (Eng. Pat. 18,504, 1891) and relates to a novel device for separating the solid and liquid constituents of sewage.

For this purpose the liquid, &c., collected from water-closets, sinks, &c., is caused to flow over a parabolically curved metallic surface, arranged vertically, convex side outwards. The liquid being spread out in a comparatively thin layer, follows the contour of the surface and is received at the lower extremity of the surface in a chute. The solid portions of the sewage, however, when they reach the centre of the curved surface, glance off, and fall perpendicularly into a special receptacle. Details and drawings are given showing the manner of adapting the above contrivance to an ordinary dwelling-house and to a street gully.—H. T. P.

### (C).—DISINFECTANTS.

*Tests of a Disinfectant for Use in Railway Sanitation.* W. T. Sedgwick. Tech. Quart. 1893, 6, 2, 143.

THE disinfectant used by the Pennsylvania Railroad Co. is stated to consist of a solution of the chlorides of zinc, copper, and mercury, together with a little turpentine to act as a tell-tale and indicate where it has been used. The specification to which it is made requires that each 8 oz. bottle shall contain 2,400 grains of zinc chloride, 120 grains of cupric chloride, 10·5 grains of mercuric chloride, and 10 drops of a mixture of equal parts of terebene and turpentine. The author examined the effect of this disinfectant upon various typical bacteria, using methods well adapted to prevent the inhibition of the growth of the bacteria by disinfectant carried over from the vessel in which they had been exposed to its action to that in which their cultivation was to be carried out; the following are the chief results arrived at.

*Bacillus typhi abdominalis.*—The Eberth bacillus of typhoid fever was killed by an exposure of 12 seconds to the disinfectant diluted to one-half its original strength.

*Spores of bacillus subtilis.*—The spores were destroyed by exposure to the disinfectant of the same strength for 17 minutes.

*Streptococcus of pseudo-diphtheria.* The destruction of the organism was effected in 12 seconds under the same conditions of dilution as before.

*Staphylococcus pyogenes aureus.*—An exposure of 10 seconds sufficed.

*Koch's cholera spirillum.*—An exposure of 10 seconds sufficed.

*Spores of bacillus anthracis.*—An exposure of 20 minutes was necessary.

A practical test of the disinfectant with a typhoid stool was made and sterilisation found to be effected in 3½ minutes. The author attributes the disinfecting action of the preparation chiefly to the presence of mercuric chloride.—B. B.

### PATENTS.

*An Improvement in the Manufacture of Sulphate of Copper.* G. F. Strawson, Newbury, Berks, and W. Fream, Downton, Wilts. Eng. Pat. 23,342, December 19, 1892.

A METHOD is described and claimed for the manufacture of sulphate of copper for insecticidal purposes, &c. The hot concentrated solution of copper sulphate obtained in the usual way is treated with one-tenth per cent. of some repellant oil, preferably eucalyptus oil, and allowed to crystallise, being continuously stirred until cold. After some time, any excess of oil is skimmed off, and the crystals dried for use.—H. T. P.

*Improvements in the Treatment of Manganates for the Production of Permanganates suitable for use for Disinfecting or other purposes and in Apparatus therefor.* W. J. Menzies, Malpas, Chester. Eng. Pat. 1213, January 19, 1893.

See under VII., page 38.

*Improvements in Compositions of Camphor with other Substances for making Solid Objects of any desired Shape or Colour.* H. F. Verdun, Pouligny St. Pierre, France. Eng. Pat. 15,767, August 19, 1894.

THE camphor is powdered and mixed with a material such as plaster, cement, or the like. The paste thus obtained may be moulded or pressed into any desired shape. By mixing camphor with wood saw-dust or pulverised leather, different articles of furniture may be manufactured from the composition. Bands to be placed round the stems or roots of vines so as to keep off phylloxera, are to be made from the composition. Any suitable colouring material may be added.—A. G. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*The Phosphoester of Benzoylamido Phenyl Acetic Acid.* F. Weiss. Ber. 26, 1699, 1699—1702.

THE above-named ester was prepared by F. Bayer and Co. of Elberfeld in 1890. It, as well as the benzoylamido-phenyl acetic acid, is employed as an intestinal disinfectant. The ester in question was prepared by the action of phosphorus oxychloride on the calculated quantities in mixture, of benzoyl amidophenyl acetic acid and phenol. It has the composition—

and forms small white needles with a melting point of 131° C., which are nearly insoluble in water. In manufacturing this substance the interesting observation was made, that if, during the action of the phosphorus oxychloride the temperature were allowed to rise above 100° C., not the desired ester, but quite a different body was formed. This latter body is formed from the ester by the separation of one molecule of water, and it appears in fine needle-shaped crystals, insoluble in water, but tolerably soluble in ether, alcohol or glacial acetic acid. These crystals melt at 101° C.—W. S.

*Basic Salicylate of Bismuth.* Schubardt. Pharm. Zeit. 1893, 38, 250.

THE following properties and tests should be responded to:—White powder, odourless, tasteless, insoluble in alcohol and water. On heating 1 grm. of the salicylate with 20 cc. of water to the boiling point, and filtering, a colourless, faintly acid filtrate should be obtained, in which barium nitrate and silver nitrate produce only a slight opalescence, and from which, after addition of hydrochloric acid, on cooling, no salicylic acid should be precipitated. On shaking 0·5 grm. with 25 cc. of dilute sulphuric acid and 10 cc. of ether, a clear solution should be obtained without any effervescence. On ignition, a residue of from 62 to 65 per cent. of  $\text{Bi}_2\text{O}_3$  should be obtained.—C. O. W.

*Occurrence of Betaine and Choline in Wormseed.* E. Jahns. Ber. 1893, 26, 1493—1496.

THE author finds that wormseed (*Artemisia Gallica*, Willd) contains about 0·5 per cent. betain and approximately 0·1 per cent. choline.

Wormseed (*Semen Contra*) is the source of santonin, the vermifuge principle of certain of the *Artemisia* family.

—A. K. M.

*Synthetic Formation of Citric Acid by Fermentation of Glucose.* C. Webber. Comptes rend. 117, 332—333.

CERTAIN moulds or fungi (of species the characteristics of which are as yet somewhat uncertain) have the power of converting sugars, especially glucose, into citric acid. Under

favourable conditions 50 per cent. of the glucose used can be converted into citric acid without formation of secondary organic products. The spores of the *citromyces* (*C. pfefferianus* and *C. glaber*) capable of producing this change are abundant in the air; by proper selection and cultivation they have been readily obtained at Hanover and at Thann (Alsace). The production of citric acid in this way is susceptible of being utilised industrially. Accordingly the process is patented.—C. R. A. W.

*A New Test for Esrine.* S. J. Ferreira da Silva.

Comptes rend. **117**, 330.

See under XXIII., page 69.

*The Metallic Compounds of Gallanilide.* P. Cazeneuve.

Comptes rend. **117**, 47—50.

GALLANILIDE, being less oxidisable than pyrogallol, admits of the formation of metallic derivatives that can be obtained in a state of sufficient purity for analysis. A disodium derivative and analogous lime, lead, and baryta compounds are obtainable, indicated by the general formula—

Zinc derivatives can be formed of three classes, viz., where 1, 2, and 3 hydroxyl hydrogens are respectively displaced by metal. Alkaloids appear to combine with gallanilide, forming insoluble compounds; thus, insoluble salts of quinine and strychnine are obtained.—C. R. A. W.

*Mercurial Salicylates.* H. Lajoux and A. Grandval.

Comptes rend. **117**, 44—47.

SALICYLIC acid, being simultaneously a phenol and a carboxylic acid, is capable of forming two classes of salts, according as the hydrogen of the phenolic hydroxyl is or is not replaced by metal; thus in the case of the mercurous and mercuric salts the compositions are—

Normal mercuric salicylate is obtained by precipitating, in the cold, a solution of a mercuric salt with normal sodium salicylate; at a boiling temperature mercuric chloride forms the basic salt, the normal salt being decomposed into basic salt and free salicylic acid; the same change ensues when the normal salt, prepared in the cold, is boiled with water. A simpler way of preparing the basic salt is to dissolve salicylic acid in boiling water and add, little by little, well-washed, recently precipitated mercuric oxide; when the yellow colour, due to the addition of one portion of mercuric oxide, has disappeared, another portion is added. The basic salt is white, and insoluble in water, alcohol, ether, and chloroform; when suspended in cold water it is not decomposed by sulphuretted hydrogen until after long standing, becoming gradually yellow, and finally black. It is slightly soluble in ammonia and in solutions of sodium chloride and potassium iodide; still more so in caustic soda. These solutions are not precipitated black by sulphuretted hydrogen; but, on standing, a yellow precipitate forms, consisting of a compound of sulphide and salicylate of mercury, salicylic acid being set free. Similarly, the basic salt, digested with a weak alkaline sulphide solution, forms the yellow double salt, which only blackens very slowly. Cold dilute hydrochloric acid is without action on the basic salt, but complete decomposition is brought about by

hot concentrated acid. Solutions of the basic salt in caustic soda or potassium iodide solution, when subjected to dialysis, leave the salt behind in an amorphous condition.—C. R. A. W.

*Cinchonine.* O. Hesse. Annalen, **276**, 88—124.

THE author has submitted cinchonine to the action of sulphuric and hydrochloric acids under various conditions, and has obtained 10 isomerides of the base  $\text{C}_{19}\text{H}_{21}\text{N}_3\text{O}_2$ , namely  $\alpha$ - and  $\beta$ -isocinchonine, apocinchonine, apocinchonine, isapocinchonine, diapocinchonine, diacinchonine, homocinchonine, pseudocinchonine and cinchonine. In addition to these there is cinchonine itself, Pum's  $\beta$ - and  $\gamma$ -cinchonine and also Jungfleisch and Léger's cinchonidine and cinchonidine.  $\beta$ -cinchonine may, however, possibly be identical with homocinchonine, and  $\gamma$ -cinchonine likewise bears a close resemblance to isapocinchonine.

The experiments described show how remarkably easily one base may be converted into another, and that such a change may actually occur during the process of the extraction of a base from the plant, or during its purification.

—A. K. M.

*Cinchonidine.* E. Jungfleisch and E. Léger. Comptes rend. **117**, 42—44.

THE supposed isomeride of cinchonine designated cinchonidine is a mixture, or possibly a compound, of cinchonidine and apocinchonine; on treatment with methyl chloride it furnishes a mixture of two kinds of crystals—one consisting of clinorhombic prisms containing  $4\text{H}_2\text{O}$ , found to be identical with apocinchonine chloromethylate; the other made up of fine needles, much more soluble in water, and identical with cinchonidine chloromethylate. The free base, although exhibiting remarkable constancy in its physical properties, notably in rotatory power, is nevertheless gradually broken up by crystallisation from alcohol; with a minimum of boiling solvent, cinchonidine separates; but with a large excess of alcohol, the crystals first deposited consist of cinchonidine, whilst apocinchonine accumulates in the mother-liquors.—C. R. A. W.

*Alkaloids of Papaveraceæ.* E. Schmidt. Arch. Pharm. **1893**, **231**, 136, 161, 174.

THE suggestion that a distinct chemical relationship exists between plants morphologically related, has not been strictly confirmed by these investigations. Of the numerous opium alkaloids, only Hesse's protopine was observed in the other papaveraceæ, *Chelidonium majus*, *Stylophoron dianthillum*, *Sanguinaria canadensis*, *Eschscholtzia californica*. Bardet and Adrian's observation of morphine in the last-named species could not be confirmed. The roots of *Sanguinaria canadensis* were found to contain the following alkaloids. (1.) *Chelerythrine*,  $\text{C}_{22}\text{H}_{17}\text{NO}_4 + \text{C}_2\text{H}_5\text{OH}$ , crystallises with one molecule of alcohol, which is not given off at  $150^\circ \text{C}$ . The hydrochloride,  $\text{C}_{22}\text{H}_{17}\text{NO}_4 \cdot \text{HCl} + 5\text{H}_2\text{O}$ , crystallises in brilliant yellow needles. The hydroiodide forms yellow needles and contains no water of crystallisation. (2.) *Sanguinarine*,  $\text{C}_{20}\text{H}_{15}\text{NO}_4 + \text{H}_2\text{O}$ , forms white needles with melting point  $213^\circ \text{C}$ . It is characterised by the blood-red colour of its salts. The hydrochloride contains five, the nitrate one molecule of water of crystallisation. (3.)  $\gamma$ -*Homochelidonine*,  $\text{C}_{21}\text{H}_{21}\text{NO}_5$ , together with  $\beta$ -*Homochelidonine* and protopine, occurs in the ammoniacal mother-liquor obtained from the precipitation of the crude alkaloids. (4.)  $\beta$ -*Homochelidonine*,  $\text{C}_{21}\text{H}_{21}\text{NO}_5$ , was obtained in minute quantities. It was also observed by Hesse in the roots of *Chelidonium majus*. (5.) *Protopine*,  $\text{C}_{20}\text{H}_{17}\text{NO}_5$ , was first isolated from opium by Hesse. Its melting point is  $270^\circ \text{C}$ . It forms colourless salts. The above formulae for *Protopine* and *Chelerythrine* were confirmed by G. König.—C. O. W.

*Investigations on Narceine.* Martin and Freund and (in part) G. B. Frankforter. Annalen, **277**, 20—58.

NARCEINE is indicated by the formula,  $\text{C}_{22}\text{H}_{27}\text{NO}_5 \cdot 3\text{H}_2\text{O}$ , the hitherto generally received formula,  $\text{C}_{22}\text{H}_{29}\text{NO}_5 \cdot 2\text{H}_2\text{O}$ , being inexact. As formerly pointed out by Alder Wright

and Beckett, it stands in very close relationship to narcotine, gentle oxidising agents furnishing the same hemipinic acid in each case; accordingly the question arises, is narcine actually pre-contained in poppyeapsule juice, or is it formed from narcotine during the processes adopted in manufacturing morphine from opium? On the whole, the authors incline to the former view. A large number of narcene derivatives are described, amongst others, metallic derivatives such as *potassium narcene*,  $C_{23}H_{29}KNO_3$ ,  $C_2H_5O$ , which crystallises with alcohol of crystallisation. Narcene contains three methoxyl groups, and has the constitution of a substituted phenylbenzyl ketone.—C. R. A. W.

*Investigations on the Alkaloids contained in the Root of Corydalis cava (Schwegg).* M. Freund and W. Josephi. *Annalen*, 277, 1—19.

The authors conclude, from their own work and that of Dobbie and Lauder, and of E. Merck, that the root of *Corydalis cava* contains the following alkaloids:—

	Melting Point.
Bulbocapnine, $C_{13}H_{19}NO_3$ .....	139°
Corydine, amorphous .....	65°—75°
Corydaline, $C_{23}H_{29}NO_3$ .....	134°
Corycavine, $C_{23}H_{29}NO_3$ .....	215°
Corytuberine, $C_{19}H_{25}NO_3$ .....	Above 200°
Corybulbine .....	208°

Corydaline forms a crystallisable hydrochloride and hydriodide; with methyl iodide it unites to form a crystalline compound, which on treatment with silver chloride and caustic potash in succession forms *methyl corydaline*,  $C_{23}H_{29}NO_3$ ; this also combines with methyl iodide. It contains four methoxyl groups, whereas bulbocapnine contains but one: probably the two are related, as indicated by the respective formulæ—

Corycavine contains no methoxyl group. Various salts of corydaline, bulbocapnine, corycavine, and corytuberine are described.—C. R. A. W.

*The Alkaloids of Gelsemium Sempervirens.* A. R. Cushny. *Ber.* 26, 1893, 1725—1727.

In this paper the author describes some of the properties of the alkaloids occurring in *Gelsemium sempervirens*. *Gelsemine* (Gerard, *Pharm. J.* and *Trans.* (3), 13), is a white, non-crystalline, strongly alkaline, bitter substance. Its hydrochloride is crystalline, easily soluble in water, slightly so in alcohol. It gives no colour reactions with nitric or sulphuric acids. But if to a solution in the latter, an oxidising agent be added ( $MnO_2$ ,  $K_2Cr_2O_7$ , &c.), an intense red colour is developed, passing gradually into green. The gold and platinum double salts are soluble in hot water, from which they crystallise on cooling. *Gelsemine* produces in frogs spasmodic contractions followed by paralysis of the extremities of the motor nerves. Analysis assigns to the hydrochloride the formula,  $C_{19}H_{23}N_3O_{14} \cdot 2HCl$ .

*Gelseminine* (Thompson, *Pharm. J.* and *Trans.* (3), 17) is colourless, amorphous, strongly alkaline, insoluble in water, soluble in alcohol, ether, and chloroform. Its salts are readily soluble, amorphous, yellowish substances. *Gelseminine* gives with nitric acid a green, and with sulphuric acid a yellow coloration, changing on addition of oxidising agents to violet and finally to green. *Gelseminine* is highly poisonous, not only to amphibia, but also to warm-blooded animals. One mgrm. of this alkaloid suffices to kill a rabbit, whilst 0.5 grm. *gelsemine* has no effect whatever upon it. The platinum double salt of *gelseminine* has the formula,  $C_{19}H_{23}N_3O_{14} \cdot HClPtCl_4$  (compare this *Journal*, 1893, 618).—H. T. P.

*Derivatives of Toly-antipyrine.* G. Liebert. *Pharm. Zeit.* 1893, 38, 251.

*Toly-antipyrine hydrochloride* is obtained as a crystalline body by passing a current of hydrochloric acid through a solution of toly-antipyrine in benzene.

*Chloral hydrate toly-antipyrine* is formed when hot solutions of molecular proportions of chloral hydrate and toly-antipyrine are mixed together. It separates as a crystalline precipitate.

*Ferric chloride toly-antipyrine* is obtained by substituting ferric chloride for chloral hydrate in the last process, alcoholic solutions being used. A precipitate is formed consisting of a yellowish-red amorphous powder, which is the ferric chloride compound referred to.

*Monobromo- and mono-iodotoly-antipyrine* are obtained by treatment of the toly-antipyrine dissolved in chloroform, with bromine or iodine, as the case may be.—C. O. W.

*Gardenia Resin.* E. Heckel and Schlagdenhauffen. *Répert. de Pharm.* 1893, 49, 115.

See under XIII., page 47.

*The Preparation of the Oak Tannins, with Special Reference to the Use of Acetone as a Solvent.* H. Trimble and J. C. Peacock. *Pharm. Jour.* 1893, 53, 317—318.

THE usual solvent for tannins is official ether, sp. gr. 0.750, which is equivalent to a mixture of alcohol and ether. Critical experiments have been made on oak bark with this solvent and with acetic ether, water, and acetone. Acetone was found to be the most suitable, and the following process is therefore recommended:—The powdered oak bark is well moistened with acetone, packed in a glass percolator, and the menstruum poured on until it begins to drop from the lower orifice, when the latter is closed with a cork, and the bark allowed to macerate for 48 hours, evaporation being prevented by covering the percolator with a glass plate smeared with vaseline. The cork is then removed and acetone poured through until the number of litres of percolate amount to one-half the number of kilos. of bark used. The acetone is then distilled off over a water-bath, at first at ordinary pressure, but afterwards under reduced pressure. The dark-coloured residue is warmed with water until nearly all of it has dissolved; the solution is cooled and filtered, and the clear filtrate diluted with water until no further precipitation occurs. The precipitate, consisting of the bulk of the anhydrides, is filtered off, and the filtrate successively agitated with acetic ether. The extracts are mixed and the acetic ether distilled off, under reduced pressure, in order to obtain the tannin in a porous condition. The product is treated with cold water, the solution is filtered, and the filtrate is again extracted with acetic ether. This process is repeated until the tannin is completely soluble in water. The tannin now possesses an odour of acetic ether, which is removed by solution in official ether, sp. gr. 0.750, and distillation of the solvent. For the removal of the last trace of resin and crystalline principles, digestion with absolute ether should follow.

It was found in some cases that by dissolving the acetone residue in a mixture of four parts of water and one part of alcohol, instead of water alone, a smaller quantity of anhydride was formed.

From a sample of powdered nut-galls commercial ether extracted 59.77 per cent. of solids, whilst acetone extracted 62.24 per cent. of the same.—A. G. B.

*The Localisation of the Active Principles of the Myronette.* L. Guignard. *Comptes rend.* 117, 861—863.

INDIGENOUS species of the family of the *Rosaceæ* contain in their stems and leaves, and especially in their roots, a nitrogenous sulphurised essential oil, apparently identical with that of black mustard. This, however, does not pre-exist as such, but as a glucoside, which becomes decomposed under the influence of the special ferment, *myrosine*, contained as cellulose distinguishable under the microscope. In

these respects the miguonettes exactly resemble the other cruciferous plants previously examined by the author; these results are entirely at variance with those previously recorded by Spatzier, who found that myrosine was not contained in the roots (though present in the aerial organs and the seed); and that the oil was present in the roots as such, and not as glucoside.—C. R. A. W.

*Geraniol.* Ph. Barbier. Comptes rend. 117, 120—122.

THE essential oil of *Andropogon Schannanthus* (Hindoo geranium oil) contains about 75 per cent. of geraniol,  $C_{15}H_{25}O$ , easily separated in an approximately pure condition by fractional distillation *in vacuo*, the impurity being a trace of a sesquiterpene, which increases its density and gives it a slight laevo-rotatory power. Pure geraniol is obtainable by converting into acetic geraniol ether by means of acetic anhydride at 150°, and saponifying the product. The ether boils at 129—130° under 14.5 mm. pressure, and has the specific gravity at 0°, 0.9388; pure geraniol boils at 126°—127° under 16 mm. pressure, and has the specific gravity at 0°, 0.9012; gaseous hydrochloric acid forms a dihydrochloride,  $C_{15}H_{25}Cl_2$ , boiling at 142°—143° under 16 mm. pressure, and breaking up into hydrochloric acid and dipentene (characterised by its tetrabromide) on boiling with acetic solution of potassium acetate. Geraniol appears thus to be the stable stereo-chemical isomeride,  $C_{15}H_{25}O$ , and linalol the unstable one.—C. R. A. W.

*Action of Sulphuric Acid on Pyrocatechol and Homopyrocatechol.* H. Cousin. Comptes rend. 117, 113—115.

PYROCATECHOL and twice its weight of sulphuric acid mixed and allowed to stand in the cold for some days become a solid crystalline mass of pyrocatechol sulphonic acid. The free acid melts at 53°—54°, and is soluble in alcohol and in ether; the barium salt is—

It yields a fine green coloration with ferric chloride, becoming red with alkalis. The potassium salt—

is very soluble in water, but insoluble in cold alcohol. If pyrocatechol and sulphuric acid be digested on the water-bath, the same sulphonic acid is formed, together with a little of a disulphonic acid. This latter is obtained in quantity by heating together on the water-bath for half an hour a mixture of one part pyrocatechol and five of fuming acid containing 30 per cent. of anhydride. The potassium salt of this is  $C_6H_3(OH)_2 \cdot (SO_3K)_2 \cdot H_2O$ . At temperatures above 100°, ordinary sulphuric acid chars pyrocatechol.

Homopyrocatechol only yields a monosulphonic acid, whether acted on by oil of vitriol or by 30 per cent. fuming acid. This acid is soluble in alcohol and ether; it melts at 93°—94°. The barium and potassium salts are respectively  $[C_7H_5(OH)_2 \cdot SO_3]_2Ba, 3H_2O$ , and  $C_7H_5(OH)_2 \cdot SO_3K, H_2O$ .—C. R. A. W.

*Oil of Spike (Lavandula Spica).* G. Bouchardat. Comptes rend. 117, 53—56.

THE essential oil examined, had the sp. gr. 0.920, and the deviation +1°, 28' for 10 cm. thickness. Its odour was disagreeable; with alcoholic potash at 100° only traces of organic salts were formed, chiefly acetate (*Lavandula vera* oil contains the acetic and valeric ethers of geraniol and linalol in quantity). On continued fractional distillation it furnished a large proportion of distillate passing over at 120°—126° *in vacuo*, or near 200° at ordinary pressure; by treatment of this with hydroxylamine in alkaline alcoholic solution and distilling off unaltered linalol, camphoroxime was obtained crystallised in the residue, borneol being contained in the mother-liquor; these were ultimately separated and recognised. From fractions passing over at 145°—150° and 150°—160° borneol was isolated. A dihydrochloride,  $C_{20}H_{31}Cl_2$ , boiling at 145°—150° was also obtained by means of hydrochloric acid, apparently the dihydrochloride of

geraniol. The fraction passing at 160°—190° was chiefly a hydrocarbon,  $C_{20}H_{34}$ , of the copaiba family. Previous experiments having shown that eucalyptol,  $C_{20}H_{34}O_2$ , is also present (boiling point near 175°), it results that five distinct isomerides of this formula are contained in oil of spike; viz., eucalyptol, laurel camphor, linalol, geraniol, and terpinol; this last being obtained as a dihydrochloride (melting at 48°—50°) from fractions passing over at 130°—135 and 135°—140°.—C. R. A. W.

## PATENTS.

*Improvements relating to the Production of Acetyl and Propionyl Compounds of Parahydroxyphenylurethanes or their Ethers.* J. F. Freiherr von Mering, Halle, Germany. Eng. Pat. 22,757, December 10, 1892.

THE parahydroxyphenylurethanes,  $HO \cdot C_6H_4 \cdot NHCOOR$ , or their ethers,  $RO \cdot C_6H_4 \cdot NHCOOR$ , are converted into their acetyl derivatives—

by heating them for about an hour with an equal weight of acetic anhydride, either under pressure or with inverted condenser; the excess of acetic anhydride is distilled off and the product allowed to crystallise. In the place of acetic anhydride either glacial acetic acid or acetic chloride may be employed. The propionyl derivatives are similarly prepared, propionic acid, anhydride or chloride, being then employed.

The products are chiefly intended for medicinal purposes, and are said to exhibit a powerful antipyretic and analgetic action.—A. K. M.

*Production of Ethers of Sulphuric Acid.* Newton and Son, London. From the Farbenfabriken vormals F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 824, January 13, 1893.

THE class of ethers to which this patent refers are mixed ethers containing one alkyl group and one aromatic group. They are obtained by the interaction of alkylsulphonic chlorides  $RO \cdot SO_2Cl$  with phenols, derivatives of phenols, naphthols, their analogues, homologues, and substitution derivatives in the presence of alkalis. These mixed sulphuric ethers are not decomposed by water, and they are stated to possess powerful and valuable medicinal properties.—A. K. M.

*Manufacture of Amido-alkylsalicylic Acid and Acetamido-alkylsalicylic Acid.* Abel and Imray, London. From Kuehler and Boff, Crefeld, Germany. Eng. Pat. 3182, February 13, 1893.

NITROMETHYL- or nitro-ethylsalicylic acid—

obtained by treating alkylsalicylic acid with nitric acid of sp. gr. 1.2, is converted into the corresponding amido-alkylsalicylic acid by treatment with the ordinary reducing agents. The corresponding acetyl-derivatives are readily obtained by treating the amido-compounds with glacial acetic acid, acetic anhydride dissolved in acetic acid, or acetyl chloride. It is preferable, however, to prepare them directly from the nitro-compounds by treatment with tin and glacial acetic acid. The products are applied to medicinal uses.—A. K. M.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Iodide of Nitrogen.* Szuhay. Ber. 1893, 26, 14, 1933—1945.

AFTER recapitulating previous researches that have been made on the formation and composition of iodide of nitrogen, and pointing out their inconclusive character, the author describes his own investigations on the same subject, together with experiments on the reactions of iodide of nitrogen with various substances.

The mode of preparation adopted by the author consisted in adding an excess of aqueous ammonia to a solution of potassium iodide nearly saturated with iodine. The product is washed with a 1 per cent. solution of sodium sulphate, as when washed with water it is somewhat decomposed, and ammonia is inadmissible because interfering with the subsequent determination of the ratio of iodine to nitrogen in the wet precipitate. By using weighed quantities of iodine and potassium iodide, and determining the amount of iodine present in the iodide of nitrogen formed and in the mixture of ammonium iodide and potassium iodide removed by the process of washing, it was found that half the total iodine entering into the reaction was present as iodide of nitrogen and half as ammonium iodide, leaving a choice of the following three equations to represent the reaction:—

Decision between these was arrived at by decomposing iodide of nitrogen with standard sulphurous acid and determining thus the quantity of  $\text{H}_2\text{SO}_3$  required for the decomposition, and also estimating the ammonia and iodide existing in the products of decomposition. The result was that equation (1) was found to represent the change, whence it appears that the composition of iodide of nitrogen prepared in the manner described above corresponds with the formula  $\text{NH}_2$ .

Having regard to the fact that nitrogen forms with negative elements compounds of acid character, the author endeavoured to replace the hydrogen in "iodide of nitrogen"  $\text{NH}_2$  by a metal. A silver compound was prepared by acting upon  $\text{NH}_2$  with silver oxide or an ammoniacal solution of silver nitrate, to which the formula  $\text{AgN}_2$  was assigned. Evidence was obtained of the existence of similar compounds containing K and Ba in place of Ag, but the corresponding lead salt was too unstable to allow of definite conclusions being drawn concerning its composition. The slightly acid character of  $\text{NH}_2$  allows of its comparison with azoimide, a body of similar constitution.

In the course of the investigation it was shown that if alcohol be added to a mixture of 5 grms. of iodine and 2 grms. of mercury amide chloride, the mixture explodes very violently in consequence of the formation of iodide of nitrogen. If a little carboic acid be present, not iodide of nitrogen, but iodoform, is produced. If amyl alcohol, chloroform, carbon bisulphide, or glycerin be added instead of phenol, gas is evolved, but there is no explosion even after 24 hours. According to Böttger, a mixture of 4 grms. of "white precipitate" ( $\text{N}_2\text{HgCl}$ ) and 6 grms. of iodine, mixed with 60 grms. of alcohol in a porcelain dish, will explode after 30 to 45 minutes. Flückiger found that four atoms of iodine and three molecules of "white precipitate" mixed together will give rise to an explosion in a very brief space of time, yielding  $\text{N}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NH}_3$ ,  $\text{HgCl}_2$ , and  $\text{HgI}_2$ . All iodides of nitrogen, from whatever sources, explode on drying.—B. B.

## PATENTS.

*Improvements in the Manufacture of Matches.* W. P. Thompson, Liverpool. From E. Lagneau, Lessines, Belgium. Eng. Pat. 3267, February 14, 1893.

THIS specification describes a methodical system of making matches, which "allows of the green shafts being inserted just as they come from the cutting apparatus, directly into the frames, and of these shafts, held in these frames, under-

going successively all the necessary operations up to the complete finishing, such operations being the drying of the green match shafts in the frames themselves and various dippings for the purpose of coating them with the various chemical ingredients."

The chief characteristic of the process is the drying of the green shafts of the matches in the frames themselves. The mechanical means employed are fully illustrated and described in the original specification. W. M.

*Improved Plugging or Tamping Compound for Blasting Cartridges, also applicable for keeping the Packages of such Cartridges Dry.* C. D. Abel, London. From the Westfälisch-Anhaltischen Sprengstoff Actien Gesellschaft, Coswig, Germany. Eng. Pat. 7572, April 13, 1893.

THIS invention relates to "a compound for plugging or tamping shot holes and for keeping packages of blasting material dry, consisting of a mixture of a neutral powder or absorbent medium, such as infusorial earth, sand, gypsum, brick earth, and the like, with a hygroscopic salt or salt solution, such as chloride of calcium, bisulphate of soda, &c., by means of which on the one hand, the deterioration of blasting materials by moisture during transport and storage is prevented, and on the other hand when it is used as tamping, the flame on firing is surrounded by vapour produced by the vapourisation of the hygroscopic substance which prevents the ignition of fire-damp."—W. M.

*An Improved Safety Explosive, and Method or Process of Manufacturing the same.* W. Evelyn-Lianet, Elsternwick, Victoria, Australia. Eng. Pat. 19,931, October 23, 1893.

THE object of this invention is to produce a safe and economical explosive. The ingredients proposed are tar, picric acid, saw-dust or wood-meal, and potassium chlorate which has been fused until it has lost one-third of its oxygen. The explosive is prepared by heating the tar to about 260° F., adding from one-third to one-half its weight of picric acid. The inventor terms this mixture "prepared tar." To two parts of this "prepared tar" is added one part of sawdust or meal—the mixing taking place in a heated vessel. The resulting product is termed "prepared sawdust." This "prepared sawdust" is mixed with the pulverised "perchlorate of potassium" in a steam-jacketed pan at 220° F. until the mass becomes quite black.—W. M.

*An Improved Gunpowder.* M. E. Leonard, Manchester. New Jersey, U.S.A. Eng. Pat. 20,066, October 24, 1893.

THIS invention relates to the preparation of a smokeless explosive. The ingredients are nitroglycerin, gun-cotton, lycopodium, and a neutraliser of free acid, such as urea or diinitrobenzol. For the United States 30 calibre rifle the patentee has found the following proportions satisfactory:—

150 parts by weight of nitroglycerin, 50 of gun-cotton, 10 of lycopodium, and 4 of urea crystals.

"For use in cannon where a further deterring and moisture proof effect is desired, 7 parts by weight of cotton-seed oil are added to the ingredients above named."—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS, ETC.

*Mercury Thermometer for High Temperatures.* M. V. Recklinghausen. Ber. 26, 1514—1517.

(Compare this Journal 1893, 865 and following abstract.)

THE author describes some tests which he made with one of the new mercury thermometers for measuring temperatures

up to 550° C. It was made of Jena glass (No. 59, III.) and the space above the mercury was filled with compressed carbon dioxide. In cases where the whole of the stem of the thermometer was not heated a correction was applied for the projecting portion. If  $t_0$  be the mean temperature and  $a$  the length of the projecting thread of mercury,  $t_1$  the observed boiling point, and 0.000156 the coefficient of expansion of mercury in glass, then the corrected boiling point  $t$  is:—

$$t = t_1 + 0.000156 a (t_1 - t_0)$$

(See Kohlrausch, *Leitfaden der prakt. Physik*, page 68, "Physical Measurements." Churchill Sect. 22 E.)

The boiling point of sulphur was determined on different days and found to lie between 447°—448° C., even although the thermometer was used to determine still higher boiling points between the observations. When the whole of the stem of the thermometer was immersed in the sulphur vapour, slightly higher results were obtained (451°·5—452°). The author therefore recommends that before determining the boiling point of any substance, the boiling point of sulphur should be taken under precisely the same conditions of experiment, and the deviation from the true boiling point (448° C. by the air thermometer) applied as an additional correction. The boiling points of several other substances, with boiling points ranging from 379° to 475° C., were also determined. By means of the new thermometer the author is trying to decide whether or not  $P_2S_3$  exists. He melted phosphorus and sulphur in the proportions given below and determined the boiling point of the mixture with the following results:—

Mixture.	Boiling Point.
$P_2 + S_3$	522°·5—525° C.
$P_2 + S_2$	545° — 546°·5 C.
$P + S_2$	516° — 518° C.

—J. S.

#### Mercury Thermometer for High Temperatures. A. Mahlke. Ber. 26, 1815—1818.

As the correction (see preceding abstract) for the projecting part of the stem of mercury thermometers for measuring temperatures up to 550° C. (this Journal 1893, 865) is sometimes as much as 20° C. wrong, the author recommends the use of an accessory thermometer, with capillary bulb, which is placed alongside the high temperature thermometer and so constructed that the correction can be read off directly.—J. S.

#### A New Stop-cock for Vacuum Desiccators. O. Ernst. Ber. 25, 1893, 1698—1699.

THIS stop-cock forms at the same time the passage for the air and is made out of glass tubing. At one end it is blown out into a stopper, the extremity of which is sealed. The other end is fluted to facilitate connection with the pump. A little above the stopper two arms are blown out, which serve to form a handle with which to turn the stop-cock. In one side of the stopper a small hole ( $a$ ) is drilled,

while in the tubulure of the desiccator is made a small notch ( $b$ ), which opens into the interior of the vessel. In one position of the stop-cock these form a connection

between the pump and the desiccator, which a slight turning of the tap is sufficient to close. The inner end of the stopper is formed into a small knob for the purpose of carrying a leathern washer in order to obviate any danger of the stop-cock falling out. A mixture of lanolin and a little vaseline is recommended for greasing the stopper.

—J. G. W.

#### Gas Analysis Apparatus. F. Fischer. Zeits. ang. Chem. 1893, 17, 511—512.

The apparatus consists of a laboratory vessel A connected by a tubulus  $c$  (see enlargement at left side of Fig.) with a measuring tube M and a levelling tube D. A is provided with a tubulus  $a$  by means of which it is coupled with a reservoir F, so that it can be filled or emptied at will. It has also a funnel  $t$  for the introduction of reagents, and a platinum spiral  $g$  for the combustion of gaseous mixtures. The side tubulus  $c$  is shaped as shown in the enlargement in the lower part of the figure, with the view of preventing any drop of liquid from the funnel  $t$  finding its way to the measuring tube M. The three-way

cock  $d$  serves for introducing the gas to be analysed into the apparatus. The platinum spiral  $g$  is carried by a stem, as shown in the figure, which works air-tight through the lower part of the laboratory vessel, so that it can be lowered out of the way of the reagents, dropped from the funnel  $t$ , when not in use. The current requisite for heating it can be supplied by a couple of Leclanche cells or by

three dry cells, there being no risk of overheating and fusion with a battery of such moderate power.

The capabilities of the apparatus and its mode of working are intelligible from the figure. It suffices to say that the author prefers to estimate CO by combustion together with the hydrogen and hydrocarbons of the gas under examination, rather than to rely on its absorption with cuprous chloride, and uses air in place of oxygen at this stage of the operations. The apparatus can be used with mercury or water according to the degree of accuracy to be attained.

—B. B.

*Apparatus for the Analysis of Gases for Carbonic Acid, Oxygen and Carbon Monoxide.* G. Pfeiffer. Chem. Ind. 16, 462—463.

A CONVENIENT form of apparatus, suitable for use in chemical works. It consists of the measuring and absorbing burette A and the aspirator B, which fits into a wooden stand heavily weighted with lead, and connected with the burette by means of a rubber tube 100 cm. long. Tap D has two rectangular perforations enabling the operator to connect the burette with the capillary tubes *x* or *y*, or to disconnect these altogether. The burette is suspended on the sheet iron strips *a a* which connect the capillary tubes with the wooden stand, and may be easily swung round the axis *x y*. The cylindrical part of the burette is charged with the absorbing material. The foot of the stand is provided with a board *b* which may be drawn out on either side and serves as an aspirator stand. The burette is prepared for use by connecting a short rubber tube provided with a funnel to the end *c*, and thus charging up the cylindrical portion as far as *e* with the absorbent solution. End *c* is then connected to aspirator B which is charged with water, slightly acidulated with hydrochloric acid. By opening clip *d*, acidulated water is admitted into the burette and accumulates above the heavier absorbing liquid; the apparatus is thus filled up as far as D.

The gas to be analysed is drawn into the burette by lowering the aspirator, and the level adjusted to O under atmospheric pressure, by opening tap D. This is then closed. By lowering the aspirator, the remaining part of the water is drawn out as far as *c* when the clip *d* is closed

and the contents of the burette agitated by rotation round the sheet iron bands. Two or three rotations are sufficient to complete the absorption, and a reading may be taken after opening *d* to equalise the levels. For a second determination D is opened, the burette filled with acidulated water and D reversed to admit a fresh quantity of gas.

By means of this burette a great number of determinations may be made in a very brief space of time, and

no fear need be entertained as to errors caused by the action of acidulated water on the absorbing material. Nevertheless, care must be taken to maintain the acid reaction of the water in the aspirator, which is preferably coloured by means of methyl orange.

Oxygen determinations are preferably carried out by means of phosphorus sticks, in which case the cylindrical part may be easily warmed up between the hands. For carbon monoxide determinations the use of a solution of cuprous chloride in hydrochloric acid, prepared according to Winkler, is recommended.

The stand C C of each burette is provided with attachments *e* and mortices *f*, enabling the operator to connect two or three burettes so as to form one apparatus.

*An Apparatus and Method for Determining the Density of Gases suitable for Industrial Purposes.* M. Meslans. *Comptes rend.* 1893, **117**, 386—390.

Attention to the analysis of gases has not hitherto entered very largely into industrial operations, it is yet desirable to know the composition of gaseous products which are given off at various stages of many of these operations, either in order to understand the nature of the reactions which take place, or to watch the development of the process.

The author believes that the determination of the density of these gaseous products will afford valuable indications of, and, in a large number of cases, with as much accuracy as analysis, will give the composition of simple gaseous mixtures. He has therefore endeavoured to devise a rapid method of determining the density of gases requiring no further skill than is required in the use of ordinary hydrometers.

His method consists in immersing two hollow spheres of equal weight and volume, the one in air, the other in the gas whose density is to be determined. The spheres are suspended from the arms of a balance and hang in separate compartments of a box with double walls of metal. The space between the walls is filled with water to establish equality of temperature in all parts of the apparatus. From the bottom of one of the compartments there issues a copper tube (see Fig.) surrounded by the water of the box. This serves to admit the gases under consideration which thus assume the temperature of the apparatus. The mixture is previously well dried and equal quantities of desiccating material are also placed in the two compartments of the box. The spheres (which are of glass or polished metal) are equilibrated in air and the gaseous mixture is then admitted. To restore equilibrium it is necessary to place a suitable

weight *P* in one of the pans of the balance. This weight *P* represents the difference in the loss of weight sustained by

the two spheres. The loss of weight sustained by the sphere immersed in air is—

$$p = \frac{0.001293 v H}{(1 + at) 760}$$

and by the other is—

$$p^1 = \frac{0.001293 v H d}{(1 + at) 760}$$

where *d* is the density of the gaseous mixture under consideration—

Thus—

$$P = p^1 - p = \frac{0.001293 v H}{(1 + at) 760} (d - 1)$$

whence—

$$d = 1 + P \frac{760}{0.001293 v} \cdot \frac{1 + at}{H}$$

The expression  $\frac{0.001293 v}{H} = K$  is the constant of the instrument, the volume *v* of the spheres being determined with great care. The density is, therefore, given by the very simple formula—

$$d = 1 + P K \frac{1 + at}{H}$$

and it is easy to draw up a table giving for all ordinary values of *t* and *H* their value of  $K \times \frac{1 + at}{H}$ .

For practical purposes the apparatus is so modified that when a slow but continuous current of gas is made to pass through it, the variations in density are indicated at any instant by the position of the pointer of the balance on a suitably divided scale.

The object which the author had in view in devising the apparatus was the systematic study of the combustion which takes place in various systems of furnaces and the regulation of the supply of air to these. The supply of air is in numerous cases ten times the necessary amount, which results in waste of fuel. The author attributes this to the ignorance of the composition of the gaseous products of combustion and the consequent neglect to properly regulate the supply of air. With a few exceptions we may consider the gases of furnaces to consist of the normal product of combustion (79 vols. of nitrogen and 21 vols. of carbon dioxide), which has a density of about 1.0875, and of air in excess. The density of the gases varies with the excess of air. The indications of the apparatus enable us to so modify the admission of air to the furnace as to prevent wasteful combustion.

The author also proposes to use the apparatus for determining the quantity of fire-damp in fiery mines.

—D. E. J.

*New Extraction Apparatus for Organic Chemical Purposes.* C. T. L. Hagemann. *Ber.* **26**, 1893, 1975—1977.

The author finds the extraction apparatus shown in the accompanying figure to give excellent results in the extraction

of liquids by light solvents. The solvent is contained in the flask B, which is heated in a water-bath and contains a small piece of porous earthenware; the latter causes boiling to occur more regularly than platinum clippings. The vapour passes up R<sub>2</sub> into a spiral tube S, pierced with small holes at its lower part; the vapour condenses and the solvent rises in small drops through the solution contained in A, forming a layer upon the surface. The solvent, as it accumulates, passes down the tube R into B. The tube R is connected to the vessel A by an india-rubber stopper and may be placed at any convenient height. The apparatus can be employed for the extraction by solvents heavier than the solution by raising the spiral S to the upper part of A,

and attaching a condenser to it; R is then enclosed by a wider glass tube open at both ends and filled with the solvent. By this arrangement the condensed solvent drops through the solution and rises into the wider tube encircling R, down which it then passes.—W. J. P.

**Oxidation of Chloroform by Chromic Acid and the Preparation of Carbonyl Chloride (Phosgene) from Carbon Tetrachloride.** H. Erdmann. Ber. 1893, 26, 1990—1994.

EMMERLING and Lengyel's method for preparing carbonyl chloride by oxidising chloroform with potassium bichromate and concentrated sulphuric acid gives a poor yield; a somewhat better yield is obtained by employing fuming sulphuric acid in the process. The equation representing the reaction given by the above-named authors is erroneous, the following being the correct one:—

The action of fuming sulphuric acid containing 80 per cent. of sulphur trioxide on carbon tetrachloride affords a far better means of obtaining carbonyl chloride. Carbon tetrachloride (100 cc.) is kept briskly boiling in a 300 cc. flask (see figure) and the fuming acid (120 cc.) allowed to drop down the attached condenser from a dropping funnel so as to come in contact with the vapour: the liberated oxychloride is washed by passing through sulphuric acid contained in a washbottle and condensed in the stoppered vessel shown in the figure, by a freezing mixture. The last portions of

the oxychloride are driven over by heating the residual liquid; the process gives a 90 per cent. yield of the crude product, which may be rectified by distillation, the distilling

flask being heated by the hand and the vapour again passed through sulphuric acid and condensed in a freezing mixture. The residue from the oxidation is a mixture of chlorosulphonic acid and pyrosulphuryl chloride; it may be separated by fractional distillation, or may be used, without separating, for sulphonations.—W. J. P.

#### Rules for the Preparation of Standard Sperm Candles.

The Metropolitan gas referees have recently issued the following particulars concerning the methods to be adopted in manufacturing standard sperm candles for photometric work:—

(1.) All candles to be used in the testing places shall be made with the materials hereinafter prescribed, and shall, when made, be examined and certified by the gas referees.

(2.) The wicks shall be made of three strands of cotton plaited together, each strand consisting of 18 threads. The strands shall be plaited with such closeness that, when the wick is laid upon a rule, and extended by a pull just sufficient to straighten it, the number of plaits in four inches shall not exceed 34, nor fall short of 32. Each wick shall be of suitable length, and looped ready for fixing in the mould. After having been bleached in the usual manner and thoroughly washed, the wicks shall be steeped in a liquid made by dissolving one ounce of crystallised boric acid in a gallon of distilled water, and adding two ounces of liquid ammonia. They are then to be gently wrung or pressed till most of the liquid has been removed, and dried at a moderate heat. Twelve inches of a wick thus made and treated shall weigh not more than 6.5, nor less than 6 grains. The weight of the ash remaining after the burning of 10 wicks which have not been steeped in boric acid, or from which the boric acid has been washed out, shall be not more than 0.025 grain. Wicks made in accordance with this prescription shall be sent to the office of the gas referees, by whom they will be examined and certified. The wicks so certified are to be used by the candle-maker in the condition in which they are returned to him.

(3.) The spermaceti of which the candles are made shall be genuine spermaceti, extracted in the United Kingdom from crude sperm oil, the product of the sperm whale (*Physeter Macrocephalus*). It shall be so refined as to have a melting point lying between 112° and 115° F. An account of the method by which the melting point of the spermaceti is to be determined is given in the appendix. Since candles made with spermaceti alone are brittle, and

the cup which they form in burning has an uneven edge, it is necessary to add a small proportion of beeswax or paraffin to remedy these defects. We therefore prescribe that the best air-bleached beeswax, melting at or about 144° F., and no other material, shall be used for this purpose, and that the proportion of beeswax to spermaceti shall be not less than 3 per cent., nor more than 4½ per cent.

(4.) The candles made with the materials above prescribed shall each weigh, as nearly as may be, one-sixth of a pound, and will be found to answer to the following test:—Immerse a candle, taper-end downwards, in water of 60° F. with a brass weight of 40 grains attached to the wick by a small piece of thread. When a further weight of two grains is laid on the butt end of the candle, it will still float; but with a weight of four grains it will sink. As the rate of burning of a candle is affected by the force with which the wick is pulled when it is set in the mould, the strain commonly applied by an experienced maker of candles has been measured, and is found to be about 24 oz. The candles shall be sent to the office of the gas referees, by whom samples from each batch will be examined and tested. Each batch of candles shall be accompanied by a specimen of the spermaceti (unmixed with beeswax) which was used in making them. Packets of candles approved by the gas referees will be sealed by them, and certified for use in the testing-places.

(5.) The candles are to be used by the gas examiners as heretofore, in accordance with the half-yearly "notifications" of the gas referees. The results are to be corrected as usual, on the assumption that for small variations the light of a candle varies directly with its consumption; and if any candle in a packet certified by the gas referees is found by a gas examiner to burn at a rate exceeding 126, or falling short of 114 grains per hour, the testings made with that candle are to be rejected.

#### *Method of Determining the Melting-Point of the Spermaceti.*

As various methods are used by different refiners of spermaceti for determining the melting-point, which lead to different results, it must be noted that the temperatures here given as the limits within which the melting-point of a sample of refined spermaceti should fall—viz., 112° to 115° F.—have been found by the following method, which is known as the capillary tube method:—

A small portion of the spermaceti is melted by being placed in a short test-tube, the lower end of which is then plunged in hot water. A glass tube drawn out at one end into a capillary tube about 1 mm. in diameter is dipped, narrow end downwards, into the liquid spermaceti, so that, when the tube is withdrawn, 2 or 3 mm. of its length are filled with spermaceti, which immediately solidifies. The corresponding part of the exterior of the tube is also coated with spermaceti, which must be removed. The narrow part of the tube is then immersed in a large vessel of water of a temperature not exceeding 100° F. The lower end of the tube which contains the spermaceti should be 3 or 4 inches below the surface, and close to the bulb of a thermometer. The upper end of the tube must be above the surface, and the interior of the tube must contain no water. The water is then slowly heated, being at the same time briskly stirred, so that the temperature of the whole mass is as uniform as possible. When the plug of spermaceti in the tube melts, it will be forced up the tube by the pressure of the water. The temperature at the moment when this movement is observed is the melting-point.

#### *Method of Washing Wicks.*

As it is found to conduce to the regular burning of candles that the wicks should have been as far as possible cleaned and freed from mineral matters, it is recommended that the candle maker, before steeping the wicks, shall wash them first in distilled water made alkaline with between 1 and 2 per cent. of strong liquid ammonia, then in dilute nitric acid containing about 10 per cent. of strong acid, and then repeatedly in distilled water.

### PATENTS.

*Improvements in Milk Testers.* M. Pedersen, Dursley. Eng. Pat. 1888, January 27, 1893.

See under XVIII. A., page 56.

*Improvements in Balances.* W. Thomson, Baron Kelvin, Glasgow. Eng. Pat. 2198, February 1, 1893.

THE invention has reference to improvements in knife edges for balances. Knife edges in this arrangement are not straight, but convex or concave in form, and called for convenience axe edges and sickle edges respectively. The sickle edges may form part of the inner edge of a ring of agate with its inner edge sharp all round. To give great hardness against lateral motion, balance beams may be supported from two sickle-edged hooks by a straight knife edge on one side and a sickle knife edge on the other.

—E. G. C.

*Improvements in the Production of Vacuum and Means for that Purpose.* J. Dewar, Cambridge. Eng. Pat. 439, January 9, 1893.

See under I., page 23.

### INORGANIC CHEMISTRY.— QUANTITATIVE.

*Separation of Lead from Tin and Antimony by Bromine.* P. Jannasch and W. Remmler. Ber. 26, 1893, 1422—1425.

CONTINUING their work on the quantitative separation of the metals of the sulphuretted hydrogen group by means of bromine vapour, the authors describe in this paper the process for the separation of lead from tin or antimony. The apparatus employed resembles a Liebig's drying tube. The body (about 20 cc. capacity) is made of hard glass and is connected at one end with an upright wide tube, and at the other with a long delivery tube bent first upwards and then down at an acute angle. Into this apparatus the weighed substances, in the form of metal or any compound, are brought, and mixed with 6—10 times their weight of sulphur. A current of sulphuretted hydrogen is then passed and the temperature raised, the sulphides finally remaining behind. The addition of 10—15 per cent. of iodine to the sulphur greatly aids the sulphurisation of refractory compounds. Bromine vapour is then led over the sulphides, the volatile bromides formed being distilled off into hydrochloric acid by heating with a small gas flame. Lead bromide remains in the apparatus; it is converted into chloride by means of chlorine water, and precipitated as sulphate. The tin is weighed as dioxide after repeated evaporation with nitric acid. No numbers are given for antimony.—J. W.

*Separation of Lead and Silver in Ammoniacal Solution by means of Chromic Acid.* By P. Jannasch. Ber. 1893, 26, 1500.

ABOUT 0.5 GRM. each of the nitrates of lead and silver are dissolved in 100 cc. of water, with addition of 2 cc. of dilute nitric acid. The boiling solution is precipitated in a large porcelain basin with a boiling 10 per cent. solution of potassium bichromate (about 5 cc. for each half grm. of nitrate); 15 cc. of dilute ammonia (1:3) are then added with constant stirring, and the resulting lead chromate precipitate warmed for 15—20 minutes on the water-bath. The precipitate is filtered off at once on cooling, washed three or four times with cold weak ammonia, and finally with water. The lead chromate is weighed as such.

The ammoniacal filtrate is carefully acidified with nitric acid and the silver precipitated as chloride. The results given are very accurate.—J. W.

**Quantitative Separation of Metals by means of Hydrogen Peroxide.** P. Jannasch. Ber. 1893, **26**, 1496—1499, 2329—2331. P. Jannasch and J. Lesinsky. *Ibid.* 2331—2336.

**Separation of Lead and Silver.**—About half a gram. of each of the salts is dissolved in 50 cc. of water, 2 cc. of strong nitric acid are added, and the lead is precipitated in the cold, as brown hydrated peroxide, with a previously prepared solution consisting of 15—20 cc. 2 per cent. hydrogen peroxide, and 15 cc. concentrated ammonia. After the precipitation, 5 cc. of cold saturated ammonium carbonate solution are added, and the whole stirred for 10 minutes before filtering. The precipitate is washed in the cold first with ammoniacal water and then with water alone. The lead may be weighed directly as oxide by placing the moist precipitate together with the filter paper in a platinum crucible, which is carefully heated in a small air bath of nickel. A stream of oxygen may be necessary to remove the last traces of carbon. Nitric acid is then added, the nitrate formed being afterwards evaporated to dryness and decomposed by careful heating.

The silver is precipitated from the filtrate by means of hydrochloric acid after evaporation and treatment with excess of nitric acid. The results are accurate.

**Separation of Silver and Bismuth.**—This separation is conducted precisely as in the preceding case, with the exception that ammonium carbonate need not be added after precipitation of the hydrated bismuth peroxide. The bismuth is incinerated as above and weighed as sesquioxide. Results fairly good.

**Behaviour of Copper Solutions.**—If a neutral solution of a copper salt is treated with dilute ammonia until the first precipitate just dissolves, an olive-green peroxide is precipitated on addition of hydrogen peroxide. No precipitation takes place if ammonia is present in excess. Tartaric acid, caustic soda, and hydrogen peroxide give a precipitate of cuprous oxide when boiled with a solution of a cupric salt.

**Separation of Lead and Copper.**—The precipitation of the lead is effected in this case with 60 cc. of 2 per cent. hydrogen peroxide and 20 cc. of concentrated ammonia in the cold, 5 cc. of saturated ammonium carbonate solution being afterwards added. The precipitate is washed first with a cold mixture of hydrogen peroxide (1 vol.), concentrated ammonia (1 vol.), and water (6—8 vols.), then with dilute ammonia warmed to 80°, and lastly with water of the same temperature. The lead precipitate is incinerated in a porcelain crucible, converted into nitrate, and weighed as oxide.

The filtrate is evaporated to drive off the excess of ammonia, treated with sulphuric acid, evaporated, diluted, and the copper contained in it finally precipitated as sulphide.

When large excess of hydrogen peroxide is used, the brown flocculent precipitate of hydrated lead peroxide changes to white pearly scales, which may be further treated precisely as in the case of the amorphous precipitate. The results are good.

**Separation of Lead and Zinc.**—The separation is effected in exactly the same manner as the separation of lead and copper. From the filtrate the zinc is precipitated as carbonate after all the ammonium salts have been removed. The zinc oxide obtained on ignition is usually contaminated with silica, which must be determined specially by dissolving the whole in hydrochloric acid, evaporating, &c. Results fairly good.

**Separation of Lead and Nickel.**—The precipitation is effected with 75 cc. of 2 per cent. hydrogen peroxide and 20 cc. concentrated ammonia, subsequent addition of ammonium carbonate being unnecessary. The lead precipitate is treated as in the case of the separation of lead and copper.

The nickel is precipitated by means of caustic soda from a hot solution containing hydroxylamine hydrochloride. Results fairly good.—J. W.

**Determination of Phosphorus by the Molybdenum Method.** F. G. Myhlertz. *Eng. and Min. J.* **56**, 339.

IN the form of a letter criticising a previous paragraph on the above subject, the author thinks it is erroneous to call the turbidity formed on dissolving the ammonium phosphomolybdate in ammonia "an impurity." By its removal, as sometimes recommended, a source of error is introduced, due to a loss of phosphorus amounting to some thousandths of 1 per cent. An examination of the turbidity invariably reveals both phosphorus and iron. It consists probably of a phosphate of iron formed by the contact of ammonium phosphate and minutely divided ferric hydrate upon dissolving the ammonium-molybdate salt in ammonia. The presence of iron is due to incomplete washing previous to dissolving. The formation of the turbidity is obviated by adding citrate of ammonia to the ammonia, when the iron is kept in solution, and, moreover, the final magnesium pyrophosphate is absolutely white, not "almost white," and also free from molybdenum. To remove the turbidity or to allow it to remain introduces an error. The former by loss of phosphorus and the latter by the introduction of iron as ferric pyro-phosphate into the ignited final product.

—A. W.

**Notes on the Estimation of Copper as Copper Sub-Sulphide.** R. Wegscheider. *Monatsh. f. Chem.* 1893, **14**, 315.

THE majority of analytical handbooks contain the statement that sub-sulphide of copper is perfectly stable at high temperatures, provided access of air be prevented, or the ignition be carried out in a current of hydrogen. Pickering, however, and after him Uhl, found that at a red heat sub-sulphide of copper is reduced to metallic copper by a current of hydrogen, sulphuretted hydrogen being formed at the same time. It appears that these statements passed quite unnoticed. A repetition of the experiments gave results which proved that at a dull red heat the interaction between sub-sulphide of copper is practically nil, but at higher temperatures reduction ensues to such a degree as to vitiate the results of the analysis. This reduction always proceeds very slowly, so that if the heating at a high temperature be of sufficiently short duration, the results obtained will be approximately correct. In order to avoid the careful regulation of the temperature required for the ignition of copper sulphide in a current of hydrogen, sulphuretted hydrogen was substituted for the latter. No reduction of the sulphide occurs under these circumstances, even at very high temperatures, but, on the other hand, it was found impossible in this way to effect a complete conversion of the copper sulphide into the sub-sulphide.—C. O. W.

**The Volumetric Determination of Copper by Means of Sodium Sulphide.** A. Borntrager. *Zeits. ang. Chem.* 1893, **17**, 517—524.

THE process of titrating copper by means of a solution of sodium sulphide is too well known to need description. The author finds that the operation should be carried out cold, as irregularities occur when the solution is used hot, as recommended by Pelouze and Kuenzel. The solution to be titrated should be ammoniacal, and the flask containing it vigorously shaken after each addition of sodium sulphide, as otherwise the precipitated sulphide may not ball together and allow the colour of the supernatant liquid to be seen. The accurate determination of the endpoint must be effected by the use of an external indicator. The author has examined the behaviour of various indicators, such as sodium sulphide and potassium ferrocyanide, depending on the disappearance of the reaction with copper, and that of an alkaline lead solution and sodium nitroprusside depending on the appearance of the reaction with sodium sulphide, and finds that one class cannot be substituted indifferently for the other. The cessation of the reactions for copper occurs appreciably before the beginning of the reactions for a sulphide. Potassium ferrocyanide and alkaline lead solution are the most sensitive indicators for their respective classes. Whichever be adopted, the standardisation of the sulphide solution and the titration of the copper solution under examination must be carried out with the same indicator.

The titration of copper with sodium sulphide can be performed in the presence of zinc, for although a white precipitate of zinc sulphide takes place on the addition of the standard solution, yet this reacts completely with the remaining copper salt on shaking, and the whole of the copper is precipitated before the zinc is permanently separated. The method is therefore valid for the analysis of zinc-copper alloys. The determination of copper in commercial preparations of copper sulphate, is conducted as follows:—5 grms. of the sample are dissolved in water, any iron present oxidised with nitric acid, the solution supersaturated with ammonia, filtered if necessary, and an aliquot portion titrated. Examples of the analysis of various mixtures sold under fancy names for agricultural use, are given, but illustrate no point of sufficient novelty to merit abstraction.—B. B.

*Electrolytic Analytical Estimation and Separation.*  
G. Vortmann. *Monatsh. f. Chemie*, **14**, 1893, 536—552.

When solutions of salts of iron, zinc, cobalt, or nickel are electrolysed under suitable conditions, the metals are precipitated quantitatively; whilst under other conditions separations may be effected, one being precipitated and another not. Bunsen cells, containing instead of nitric acid a saturated solution of potassium dichromate acidulated with sulphuric acid, serve conveniently as electromotors; or preferably small accumulators of 2 volts and 25 ampère-hours power. Two of these are arranged in series as indicated in Fig. 1, where B is the battery, A an ampère-

Fig. 1.

meter, W a variable resistance, and Z the decomposing cell containing the fluid to be electrolysed. When the switch contact-maker C is in the position indicated, the current simply flows through W and Z; but when placed in the position indicated by the dotted line so as to make contact with Z, the ampèremeter A is also in circuit; the resistance of this is practically inappreciable as compared with the rest of the circuit, so that sensibly the same current flows whether A is included in the circuit or not; A is switched in when a current reading is to be made, but is otherwise left out of circuit to avoid damage through over use. The amount of resistance, W, included, depends on the current-density required, i.e., on the amperage per 100 sq. cm. of cathode surface (written N.D. 100 for shortness = normal density per 100 sq. cm.); thus with a cathode consisting of a platinum dish exposing a surface of 125 sq. cm., to obtain a current density of say 0.4 ampère per 100 sq. cm., or N.D. 100 = 0.4 ampère, the resistance must be so adjusted that the current flowing is 0.5 ampère.

Well silvered copper capsules may be employed as cathodes, conveniently of such dimensions as to weigh about 45 grms., holding 150 cc., and exposing about 115 sq. cm. of surface. Fig. 2 represents another form of cell, where the containing vessel is a glass dish, X; the cathode, a silvered copper disc, 5 cm. diameter, furnished with a silvered copper wire 5 cm. long, fixed at the centre of the disc perpendicularly to its plane; and the anode a strip of platinum foil with a platinum wire attached. Platinum discs instead of silvered copper ones are more convenient in certain cases. When the electro-deposition is judged to be complete, the cathode is removed from the fluid, disconnected, washed with water, dried, and

weighed; a similar one is coupled up in its place, the current being passed as before; and so on, until no more gain

Fig. 2.

in weight of the cathode is observed. In order to avoid loss by detaching particles of metal, the cathode is preferably dried inside a pair of watch glasses held by a spring clip, Fig. 3, the upper watch glass having a small

Fig. 3.

hole drilled through its centre to enable the wire to project, and the clip being furnished with a corresponding notch.

Test experiments made with known weights of different metallic salts yielded very satisfactory numbers. Thus, with zinc salts dissolved in caustic soda containing tartrate (N.D. 100 = 0.3 to 0.6 ampère), sensibly exact valuations of the quantity of zinc present were obtained by weighing the metal thrown down on the cathode; and similarly with iron from a similar solution (N.D. 100 = 0.3 to 1.0 ampère). With cobalt, potassium iodide must also be added, otherwise cobalt peroxide is thrown down at the anode; with this precaution and using a concentrated soda solution, fair values are obtained when N.D. 100 = 0.3 to 0.6 ampère. With nickel, the solution with caustic soda and tartrate does not deposit metal at the cathode, although a portion is thrown down as peroxide at the anode; this may be obviated by adding potassium iodide. In potassium cyanide solution only incomplete precipitation as peroxide is brought about; but all the metal present may be obtained as such at the cathode by employing excess of sodium carbonate along with tartrate or citrate as the solution (N.D. 100 = 0.3 to 0.4 ampère). By taking advantage of these differences, nickel may be separated from zinc, iron, and cobalt, the latter being deposited from caustic soda and tartrate solution, whilst the nickel is not thrown down. In similar fashion, zinc and iron may be separated, using caustic soda and tartrate solution, and a platinum dish as cathode. The iron is first thrown down (N.D. 100 = 0.3 to 0.8 ampère) along with a little zinc, from which it may be freed by redissolving and repeating the electrolysis. Another method is to dissolve in excess of potassium cyanide, when zinc only is deposited (N.D. 100 = 0.3 to 0.6 ampère), the ferrocyanide produced not being decomposed by the current. Cobalt, nickel, or copper may be determined in presence of iron by adding excess of ammonia and electrolysis; the precipitated ferric oxide is not decomposed, but need not be filtered off, the other metal being obtained free from iron as deposit on the cathode.—C. R. A. W.

*The Action of Zinc and Magnesium upon Metallic Solutions and the Determination of Potassium thereby.* A. Villiers and F. Borg. *Comptes rend.* 1893, **116**, 1524—1527.

THE method of determining metals by their precipitation in the metallic state by the action of zinc or magnesium

upon their solutions, is practically confined to a limited number, e.g. copper and platinum, and is not without drawbacks, since the precipitates are apt to contain the precipitating metal in the form of an alloy. The purity of the precipitating metal has an influence on the quantity of the metal precipitated, which is not proportional to the amount of foreign metal present. Thus a sample of zinc prepared by the electrolysis of an ammoniacal solution of the sulphate, precipitated 100·92 per cent. of the theoretical quantity of platinum when allowed to act upon a solution of the chloride; another sample, that had been distilled and contained only traces of carbon, precipitated 110·39 per cent., and a third, of commercial quality containing 1·1 per cent. of foreign matter, precipitated 119·12 per cent. of platinum. Magnesium, on the other hand, in the form of ribbon, such as is commonly sold, can be used for determining copper, gold, platinum, or potassium, the last-named having been first obtained as potassium platino chloride. (Commercial aluminium, which would be in some respects convenient as a precipitant, is too impure for analytical use.) The precipitation of copper can be carried out in a slightly acid liquid in the presence of metals of the alkalis and alkaline earths, the precipitate being granular and easy to wash. In the presence of zinc the estimation is inaccurate, as alloys are formed even when the liquid is sharply acid with hydrochloric acid. In the case of potassium, separation is effected as usual as in the form of potassium platino chloride which, is then washed, dissolved in boiling water, the solution made slightly acid with hydrochloric acid, and treated with successive fragments of magnesium until the latter is no longer discoloured while dissolving. The platinum does not stick to the sides of the beaker and is easy to wash free from soluble salts, and may be ignited and weighed in the customary manner. This method of reducing potassium platino chloride is preferable to the use of sodium formate or of formaldehyde. The authors point out that when the platinum instead of the original precipitate is weighed, the accidental presence of the double bromide replacing a portion of the chloride does not affect the accuracy of the results.—B. B.

See under XX., page 57.

*A New Test for Eserine, and a Green Colouring Matter derived from that Alkaloid.* S. J. Ferreira da Silva. *Comptes rend.* 117 330—331.

A FRAGMENT of eserine (or a salt thereof) the size of a grain of sand is placed in a porcelain capsule and dissolved in a drop or two of fuming nitric acid. The clear yellow solution becomes darker and finally orange on heating on the water-bath; on evaporating to dryness with stirring, the residue becomes a pure green substance soluble in water or strong alcohol with green colour. From these solvents it separates, apparently unchanged, on evaporation. Sulphuric acid dissolves it to a green-coloured non-fluorescent solution. 0·005 grm. of alkaloid can thus be readily detected. The author proposes to term the green colouring matter *Chloreserine*.—C. R. A. W.

#### *Detection of Nitronaphthalene in Mineral Oils.*

N. Leonard. *Chem. News*, 68, 297.

NITRONAPHTHALENE, the  $\alpha$ -derivative, is frequently added to mineral oils for the purpose of removing the fluorescence

or "bloom." The following method for its detection depends upon the reduction of nitronaphthalene to naphthylamine.

A small quantity of the oil is gently warmed with zinc dust and dilute hydrochloric acid, and the mixture agitated from time to time. During this process the fecal odour characteristic of  $\alpha$ -naphthylamine will be perceived. After the reduction is complete, the acid aqueous liquid is drawn off by the aid of a separator. A portion of this liquid, when neutralised with ammonia, gives with boric chloride a blue precipitate, which rapidly becomes purple. The remainder of the solution may be rendered alkaline with soda and extracted with ether. The latter is then evaporated, and the residue dissolved in a little alcohol. On the addition of a drop of a solution of sodium nitrate, acidified with acetic acid, a yellow colour is produced, which is changed to crimson by hydrochloric acid.

#### *The Use of Furfural for the Detection of Sesame Oil in Oil Mixtures.* A. Villavechia and G. Fabris. *Zeits. ang. Chem.* 1893, 17, 505—506.

THE well-known reaction with sugar and hydrochloric acid which has long been in use for the detection of sesame oil has been studied by the authors, who have identified various constituents of the oil other than the glycerides forming its bulk, and now give a description of such bodies as they have succeeded in isolating. By preparing a barium soap from sesame oil, extracting with alcohol, evaporating the extract to dryness, and again extracting with petroleum ether, the following substances have been obtained.

(1.) A higher alcohol of the formula  $C_{25}H_{52}O$ , with a melting point of  $137^{\circ}C$ , and a rotatory power of  $[\alpha]_D^{20} = -34^{\circ}23'$  where  $c = 5\cdot013$ .

(2.) A crystalline substance of the formula  $C_{11}H_{22}O_2$ , with a melting point of  $123^{\circ}C$ , and a rotatory power of  $[\alpha] = +68\cdot36$  where  $c = 24\cdot15$  in chloroformic solution. This substance is called by the authors *sesamin*. A similar body has been isolated from sesame oil by Tocher (*Chem. Zeit.* 1893, 121), and has had assigned to it a melting point of  $118^{\circ}C$  and the formula  $C_{15}H_{30}O_2$ .

(3.) A thick, non-crystallisable oil, free from nitrogen, and containing the substance which causes sesame oil to give its characteristic reaction with sugar and hydrochloric acid. A very small quantity of this substance when dissolved in alcohol gives a strong crimson colour with these reagents.

The authors attribute the colour reaction to the agency of furfural produced by the action of hydrochloric acid on sugar, and accordingly substitute the former for its raw materials in carrying out the reaction.

Inasmuch as furfural itself gives a violet shade with hydrochloric acid, it is necessary to use a dilute solution, e.g. 2 per cent., in alcohol. 0·1 cc. of the furfural solution is placed in a test-tube and 10 cc. of the suspected oil and 10 cc. of hydrochloric acid, sp. gr. 1·19, added, the mixture being shaken for half a minute and allowed to settle. Should sesame oil be present, even in smaller quantity than 1 per cent., the aqueous layer at the bottom of the tube becomes of a definite carmine colour. In the absence of sesame oil the lower layer is either colourless or has, at most, a dirty yellow colour, which may appear when a rancid olive oil is being tested. A modification of the test consists in using only 1 cc. of hydrochloric acid, and, after the shaking mentioned above, inducing the separation of the oily and aqueous layers by the addition of 10 cc. of chloroform. The process has been tried on a number of animal and vegetable oils, and its reliability ascertained.

—B. B.

#### *Note on an Abnormal Melting Point.* E. J. Bovan. *Analyst.* 1893, 18, 286—287.

IN the course of an examination of a crystalline fatty body obtained from pure lard by fractional crystallisation from ether, the melting point was determined by filling capillary tubes with the molten substance and proceeding in the

usual manner. When an observation was made with a tube which had been filled only a few minutes previously the melting point of the substance was found to be 47°; but when a tube which was filled at the same time was used for an observation on the following day the melting point was found to be 61.5°. After the substance had become solid in this second tube, it was found to immediately melt when the tube was immersed in water at 50°. Other experiments made with test-tubes internally coated with the substance, showed that after standing for 24 hours the melting point was above 50°; by melting one-half of the substance in such a tube, allowing it to solidify, and plunging the tube into water at 50°, this half melts whilst the other half remains solid.

It is thus apparent that the substance has two widely differing melting points; that it passes slowly and spontaneously from the state of low melting point to that of high melting point; and that the change from high melting point to low melting point can be brought about rapidly by heating.

When the temperature of the substance is gradually raised the passage from low to high melting point is procured. Thus, a tube of the recently-heated substance is immersed in water at 43°: the substance remains solid, but melts when the temperature of the water has reached 47°; when the temperature rises to 53° the substance is again solid, and finally melts at 62°. Compare *Allen's Commercial Organic Analysis*, 3 (2), 570.—A. G. B.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Adulteration of Olive Oil.* V. Oliveri. *Le Staz. speriment.* agr. ital. 1893, 24, 387.

See under XII., page 45.

*The Analysis of Beeswax.* G. Buchner. *Chem. Zeit.* 1893, 17, 918.

Hübl's method is, for practical purposes, the easiest and best for the analysis of beeswax. It is, however, possible to produce mixtures containing no trace of beeswax, which still give normal results by Hübl's method. Such a mixture may contain, for instance, 35 stearic acid, 165 Japan wax, 300 ceresin or paraffin wax. Such mixtures may even show the proper melting point and right specific gravity. In the first instance the wax should be remelted in distilled water, and if the latter exhibit an acid reaction (as is often the case with bleached wax), this operation must be repeated several times. The dried wax is then subjected to Hübl's test.

*A wax giving normal numbers.*—Acid number (19—21), 20; ether number (73—76), 75; saponification number (92—97), 95; acid number (3.6—3.84), 3.75. This may be a pure beeswax or a mixture. To decide which, the following addition tests are applied:—

1. *Stearic acid test.*—Boil 1 gm. of wax with 10 cc. of 80 per cent. alcohol, cool to 18° or 20° C. filter, add water to the filtrate and shake. Stearic acid separates out in flakes and floats on the surface; the liquid becomes clear, 1 per cent. of stearic acid may be detected in this manner. If from 7 to 8 per cent. of the acid are present, it separates out as a cream-like mass.

2. *Rosin test.*—5 grms. of the wax are boiled for one minute with about 20 grms. of nitric acid (sp. gr. 1.32—1.33), an equal volume of water and subsequently excess of ammonia are added, and the whole is filtered. The filtrate is yellow if the wax be pure; reddish brown, if resin is present. The method will indicate the presence of 1 per cent. of resin.

3. *Glyceride test.*—The residue obtained after the Hübl test, whilst still warm, is evaporated on the water bath until all the alcohol is expelled. Water is then added, the solution is filtered, concentrated, and tested with potassium bichromate. The odour of acrolein indicates glycerol.

4. If the above three tests give negative results, the Hübl test having given normal figures, no ceresin or paraffin wax can be present, and the sample may safely be pronounced pure.

*B. Wax not giving normal numbers with Hübl's test.*—In this case, the wax has certainly been adulterated, except in cases where only the acid number is too high, and in absence of stearic acid or resin. (With chemically bleached wax, the acid number may rise as high as 24). The nature of the adulterant is estimated by the above mentioned tests and their quantities calculated from the figures obtained by Hübl's test. In certain cases, an estimation of the glycerol and of the paraffin wax by Buisine's method, may be desirable. (*This Journal* 1892, 756, 471, 729, 860, 575, 165, also 1890, 771, and 1888, 871).—C. O. W.

*Contributions to the Analysis of India-Rubber Substitutes.* R. Henriques. *Chem. Zeit.* 1893, 17, 916.

See under XIII., page 48.

*Deductions from the Analysis of India-Rubber Articles.* II. R. Henriques. *Chem. Zeit.* 1893, 17, 707.

In a former paper (*this Journal*, 1893, 467) it was shown that mixtures of india-rubber and such substitutes as are prepared by the action of sulphur or chloride of sulphur upon fatty oils, can be qualitatively separated by means of alcoholic potash. In a later paper the nature of these rubber substitutes was investigated (*this Journal*, 1894, see page 47), and it was found that the characteristic component of the "white substitute" is the large quantity of chlorine it contains, while the "black substitute" contains much more sulphur, but no chlorine. With one exception, presently to be mentioned, no chlorides are used at present, or are ever likely to be used in the manufacture of india-rubber articles. The chlorine which alcoholic potash extracts from india-rubber articles, together with the substitute, can, therefore, decide the question whether "white" or "black" substitute has been present. The percentage of chlorine in the finished article is, however, much less than it ought to be according to the amount of substitute present. Two samples, containing respectively 5.3 and 12 per cent. of substitute, were found to contain respectively only 0.5 and 0.37 instead of 3.7 and 0.9 per cent. of chlorine. Evidently in the vulcanisation process a large quantity of chlorine is liberated in some form. If the substance extracted from the india-rubber contain no chlorine, it may either be derived from "black substitute" or consist of free oil. In the case of the extract being derived from "black substitute" it must at least contain 10 per cent. of sulphur, but if it consist of free oils, at most only traces of sulphur will be present, as it was ascertained by special experiments that free sulphur at vulcanisation temperature has no perceptible action upon oils. An estimation of the chlorine and sulphur in the alcoholic extract permits the analyst to pronounce as to the presence of "white substitute," "black substitute," or sulphur. If, however, the rubber article has been vulcanised with chloride of sulphur, the india-rubber combines with the chloride of sulphur much in the same way as vegetable oils do, and contains both sulphur and chlorine in about the same proportions in which they form chloride of sulphur. The analysis of two samples of thin rubber sheeting prepared from para-rubber and vulcanised with chloride of sulphur gave the following figures:—

	I.	II.
	Per Cent.	Per Cent.
1. Ignition residue of crude rubber.....	0.46	0.46
2. Sulphur.....	5.19	0.5
3. Chlorine.....	5.61	0.57
4. Extracted by alcoholic caustic soda....	2.9	2.2
5. Ignition residue of extract.....	0.67	0.90

A considerable quantity of the extract consisting of sulphur and chlorine, it follows that india-rubber vulcanised by Parkes' method yields very little extract to alcoholic caustic soda, and india-rubber articles of this description can be analysed by the methods as those vulcanised by the ordinary process. Sample I. was over-vulcanised and rather hard, Sample II. was under-vulcanised and still somewhat sticky. The analysis of a sheet of cut rubber before and after vulcanisation gave the following figures:—

	Cut Sheet Rubber.	
	Unvulcanised.	Vulcanised.
	Per Cent.	Per Cent.
1. Ignition residue.....	0.18	0.18
2. Sulphur.....	..	1.07
3. Chlorine.....	..	0.89
4. Extracted by alcoholic soda ..	1.94	1.66
5. Sulphur in extract.....	..	0.57
6. Chlorine in extract.....	..	0.55
7. Rubber extracted.....	1.94	0.54

A number of commercial articles manufactured from cut sheet (patent) rubber gave the following figures:—

	I.	II.	III.
	Per Cent.	Per Cent.	Per Cent.
1. Ignition residue.....	0.67	..	0.2
2. Sulphur.....	3.68	2.37	1.86
3. Chlorine.....	3.63	2.51	1.33
4. Residue on extraction.....	84.3	92.1	94.5
5. Ignition residue of extract.....	1.8	..	0.88
6. Sulphur in 4.....	1.92	1.77	0.83
7. Chlorine in 4.....	1.31	1.54	1.17
Dissolved:—			
S + Cl.....	4.08	1.57	1.19
Organic matter.....About	12.50	6.5	5.0

Sample No. I. was a specimen of cheap gas tubing (black). Nos. II. and III. were similar tubing, but of better quality. From the alcoholic extract of Sample I., by precipitation with acid and extraction with ether, a heavy oil was separated which on analysis gave the following figures:—

	Per Cent.
Sulphur.....	6.29
Chlorine.....	0.55
Iodine absorption.....	92.0

It will be observed that these figures are almost identical with those obtained in analysing the fatty acids of the substitutes made from colza oil or cotton-seed oil, and there is no doubt that such substitutes were contained in the above samples. It is frequently believed that articles made of cut sheet rubber must necessarily be pure, but as a matter of fact they may contain as much as one-third of the before-mentioned substitutes.—C. O. W.

*Saffron and its Adulterants.* E. Vinassa. Archiv. der Pharm. 1892, 231, 353; Diagl. Polyt. J. 290, 47.

To detect adulteration in commercial saffron, the author recommends the employment of the following tests:—

I. *Microscopic and Micro-Chemical Examination.*—A small quantity of the sample is mounted in paraffin oil and examined under the microscope; if all the small particles

are equally coloured, the sample is genuine, but the presence of white or yellowish grains, resembling those of saffron in form, will indicate adulteration with already extracted saffron.

Pure saffron, treated with concentrated sulphuric acid and examined under the microscope, exhibits blue markings, which gradually change to a dirty violet colour, whereas most of its adulterants show characteristic violet or cherry-red ones.

If the sample be clarified with chloral hydrate and then extracted with water, examination with the naked eye will detect admixture with the grosser adulterants, such as sandal wood, logwood, and safflower. On examining a little under a high power, the form of the pollen grains, being most characteristic of the particular species of plant, will afford a good idea as to the genuineness of the sample or the nature of its adulterant, as will also the presence of hairs, crystals, &c.

II. *Chemical Examination.*—This consists in estimating the amounts of ash and water. A genuine sample should not contain more than 15–16 per cent. of water and 8 per cent. of ash. A larger amount of ash indicates the presence of sand, gypsum, or heavy spar.

For the estimation of the colouring power of the saffron, Procter's method may be employed. This consists in extracting 1 part of saffron with 1,000 parts of water for four hours, and filtering off 50 cc. A 10 per cent. solution of potassium bichromate is then added to 50 cc. of water until the colour of the mixture is equal to that of the saffron extract. As a rule 5 to 6 cc. of the potassium bichromate solution should be necessary.

III. *Physical Examination.*—If the saffron be strewn on the surface of water, contained in a shallow dish, the presence of dark points will indicate adulteration with sandal wood, logwood, or safflower. Goppelsroder's method of capillary analysis is of great value in this connection.

—J. G. W.

## ANALYTICAL AND SCIENTIFIC NOTES.

*Electrical Transport of Heat in Electrolytes.* H. Bagard. Comptes rend. 117, 97–100.

By means of the arrangement shown in the figure the author has been enabled to demonstrate that the electrical

transport of heat discovered for metals by Thomson in 1854 can also occur in certain saline solutions. B<sub>1</sub> and B<sub>2</sub> are two glass vessels closed by corks through which pass two glass tubes, I and II, each 1 cm. diameter and 6.5 cm. long, these being inferior prolongations of the upper reservoir A. The lower ends of these tubes are closed with

parchment paper;  $a_1a_1'$  and  $b_1b_1'$ , also  $a_2a_2'$  and  $b_2b_2'$ , are side tubes fused to I and II respectively, and communicating with them by means of very fine holes at  $a_1$  and  $b_1$ ,  $a_2$  and  $b_2$  respectively.  $d_1, d_2$  are two electrodes, by means of which a current can be passed from  $B_1$  to  $B_2$  through I, A, and II, or in the opposite direction. The whole apparatus being filled with the fluid to be experimented with, the upper part is enclosed in the centre of an annular metal box forming a steam jacket, whilst the lower vessels  $B_1$  and  $B_2$  are kept relatively cool by means of a current of water, the tubes I and II being thickly coated with non-conducting material. By-and-bye an equilibrium of temperature is attained amongst the various layers of fluid; at this stage the resistance-ratio of the two columns of fluid between the holes  $a_1, b_1, a_2, b_2$  is ascertained. The current being then passed through the apparatus, heat is developed (Joule effect), which may cause some slight alteration in the value of the resistance-ratio of the two columns owing to want of perfect symmetry; but even if this be the case, the new ratio must be independent of the direction of the current. If, however, a Thomson effect be produced, it will affect each tube in the opposite way, since the current ascends one tube and descends the other; so that the resistance-ratio will be altered in a way dependent on the direction of the current; according as the current passes one way or the other the numerical value of the resistance-ratio will increase or diminish. With a solution of zinc sulphate (23.7 per cent.) the values obtained indicate that the substance is *positive*, i.e., heat travels in the direction of the current through a solution of this salt. Analogous results are obtained with zinc chloride and copper sulphate; but with nickel sulphate the resistance-ratio does not measurably alter, so that with this salt the effect is much more feeble.

—C. R. A. W.

*On the Electric Transference of Heat.* L. Houllévié. Comptes rend. 1893, **117**, 516—518.

It follows from certain experiments by Thomson, Remsen, Rowland, and others that the difference of potential between a conducting body and iron depends upon whether the latter is neutral or magnetic. Assuming this, let us consider a circuit formed by iron and another conductor which is not magnetic, e.g., copper, and let us suppose that the two iron-copper junctions are infinitely far apart. The electromotive force of the system is necessarily zero. But if we place a magnet near one of the junctions, its difference of potential is modified by the magnetism of the iron, while at the other junction its value remains constant. A current should therefore be set up; but this is impossible, because there is no permanent absorption of energy. It is therefore necessary that the variation of the electromotive force produced at one of the junctions in consequence of the magnetisation should be compensated in the rest of the circuit. This compensation must occur in the magnetic parts and it is natural to assume that it is of the nature of a continuous variation of potential between the sections which are unequally magnetised. The author has endeavoured to verify this result experimentally. The essential part of his apparatus consists of a strip of soft iron 1 cm. broad, 0.6 mm. thick, and 50 cm. long, bent into two parallel branches along which the current is passed, while a magnet is used to produce the difference of potential sought for. To detect the effect he employs a thermo-electric pile formed of four bismuth-copper elements arranged in horse-shoe shape. The thermo-electric pile is connected up to a Thomson galvanometer, the sensitiveness of which is such that an E.M.F. of one-millionth of a Daniell cell introduced into its circuit produces upon its scale a deflection of seven divisions.

If a current is passed along the iron strip a considerable permanent deflection (about 50 divisions) is at once produced; this arises principally from the difference of the heating effects (due to the term  $CR^2$ ) at the two poles of the thermo-electric pile. When the direction of the current along the iron strip is reversed, a small deflection (about one division) is observed. This is instantaneous and evidently arises from a very slight (but unavoidable) modification of the magnetic field in the neighbourhood of the

galvanometer produced by the reversal of the current. The galvanometer, however, presently exhibits a slow deviation, quite distinct from the preceding, and amounting in a few minutes to about three divisions, after which the needle remains at rest in its new position. The author is of opinion that this slow deflection reveals the effect expected. There is always an evolution of heat as the current passes from neutral regions to magnetised regions, and an absorption of heat in the contrary case. Hence there exists between two sections unequally magnetised (and in consequence of the magnetisation) a difference of potential in favour of the section which is less strongly magnetised.

—D. E. J.

*The Relations between the Optical Rotatory Powers of Cinchonidine and its Salts, and the Influence of Solvents on Rotation.* Carl A. Schuster. Monatsh. f. Chemie, **14**, 1893, 573—595.

THE author has prepared cinchonidine hydriodide and hydrobromide, salts not hitherto described, and has examined the rotatory powers of solutions of these salts, as also of cinchonidine hydrochloride, acetate, sulphate, and nitrate, and of the free alkaloid itself, using (a) absolute alcohol, (b) 50 per cent. spirit, and (c) water, as solvents. The rotation is always to the left, and is relatively greater in amount in a more dilute solution than in a stronger one; excepting with the sulphate in 50 per cent. spirit, where the opposite is the case; and with the acetate in absolute alcohol, where the specific rotatory power at first rises and then falls with increasing dilution, possibly through dissociation of the acid and base.

Excepting in the case of the sulphate, the rotation is least in absolute alcohol, and greatest in 50 per cent. spirit, intermediate values being obtained in aqueous solution (same degree of concentration throughout). With the sulphate the rotation is greatest in 50 per cent. spirit as before, but less in aqueous than in absolute alcoholic solution.—C. R. A. W.

## New Books.

DICTIONARY OF THE ACTIVE PRINCIPLES OF PLANTS; ALKALOIDS; BITTER PRINCIPLES; GLUCOSIDES: THEIR SOURCES, NATURE, AND CHEMICAL CHARACTERISTICS, WITH TABULAR SUMMARY, CLASSIFICATION OF REACTIONS, AND FULL BOTANICAL AND GENERAL INDEXES. By CHARLES E. SOHN, F.I.C., F.C.S. London: Baillière, Tindall, and Cox, 20 and 21, King William Street, Strand. 1894. 10s. 6d.

THIS work is an oblong-shaped 8vo. volume, strongly bound in dark green cloth, and containing preface, which points to the need of such a work alike for the analyst, professor, research chemist, student, and manufacturer, and to the fact that descriptions are given in the text of some 600 alkaloids, bitter principles, and glucosides, an introduction with explanatory notes, as to the method of using the dictionary, and subject matter, largely tabular, extending over 167 pages. The work closes with two indexes, the last of Substances, Reagents, &c., and the one preceding it, of Botanical terms. A list of Addenda follows the latter index.

Part I. of the work itself is in dictionary form, and herein are grouped together the constituents either of one plant or of a number of botanically or chemically allied plants. In this section the botanical details, general, physical, and chemical details, solubility and reactions, and colour tests, are given.

Part II. is a tabular summary for the purpose of contrasting one compound with another for analytical and other purposes.

Part III. A classification of reactions for the special use of analysts, showing what compounds are known to respond to a given test.

TABELLARISCHE Uebersicht über die künstlichen organischen Farbstoffe und ihre Anwendung in Färberei und Zeugdruck. Von Dr. Adolf Leinze. Dritte Lieferung. Berlin: Verlag von Julius Springer. 1893. London: H. Grevel and Co., 33, King Street, Covent Garden. 6s.

The third part of this tabular review of the progress of the application of the artificial colouring matters to dyeing and calico-printing, has just appeared. The record commences with "Brilliant yellow," and concludes with "Congo brown." It involves the novel expedient of adopting a tabular column consisting of dyed and printed specimens, the other columns of the table containing printed descriptive matter. Below each specimen is given the percentage of colouring matter used in the dye-bath, to produce the tint exhibited, adding at the same time the condition of the dye-bath after the process as to exhaustion or non-exhaustion. In an adjoining column are given data referring to the modes of using the dye; its durability and fastness, solubility, and modes of recognition by test. Another column contains the trade name, with letters signifying the maker's name, and the adjoining column gives the index number in Schultz and Julius' tables, where all information and literature of the colouring matter, can be found, and the final column contains the number of the colour referred to, in the present tables under consideration.

## Prizes.

PROGRAMME OF PRIZES offered by the SOCIÉTÉ INDUSTRIELLE DE MULHOUSE, 1894. Pamphlet, 68 pages. 1893.

THE Industrial Society of Mulhouse offers five foundations and a very large number of medals for competition in 1894. The founders receive a medal along with a sum of money varying between 400 and 5,000 francs. As a rule the medals are of bronze or silver, and in a few instances the medallists are also presented with a sum of money. The conditions which must be observed by intending competitors are as follows:—

1. Foreigners as well as natives are admitted to the competition. The members of the administrative council and the committees of the industrial society are alone excluded.

2. Memoirs, drawings, models, and samples must have the author's motto attached, and should be forwarded, postage paid, before the 15th of February 1894, to the President of the Industrial Society of Mulhouse, along with a sealed letter containing the author's exact name and address.

3. The Society only makes itself acquainted with the names of the successful competitors; at the same time it reserves the right of opening the sealed letter in cases where any additional or indispensable information is necessary.

4. Each competitor, by the mere fact of entering the competition, acknowledges the decision of the Society to be final.

5. Where necessary the Society will send deputies to the works in order to examine the plant and processes.

6. If a problem is not completely solved the Society may award, for the sake of encouragement, a larger or smaller fraction of the prize offered.

7. If several competitors are nearly equal, the prize will be divided between them, equally or unequally, according to the relative values of the solutions.

8. Each competitor retains the right of patenting an invention, but the Society reserves the right of publishing, wholly or in part, the memoirs which have been addressed to it.

9. According to the legislation in most countries, a discovery, invention, or application is not considered new when, in that country, and previous to the date of application for a patent, it has received such publicity that it has already been in use. In consequence, authors are

recommended to obtain letters patent for their discoveries before entering the competition, as the Society declines all responsibility in the matter. In case a prize is awarded for an invention which has not been patented, the author may demand that the publication of his memoir be deferred.

10. The Society does not return memoirs which have been sent in for competition, but the authors may retain copies. Drawings and models which accompany memoirs are retained until a suitable opportunity for returning them presents itself.

11. The relative values of the medals which are awarded by the Society are distinguished as follows:—

Medals of honour.  
Silver medals.  
Bronze medals.

12. The Society reserves the right to award prizes for any work which may be deemed worthy, even although the problem is not included under any of the sections mentioned in the programme.

There are 64 prizes offered in the section of chemical industry, 37 in mechanical industry, 7 in natural history and agriculture, 8 in commerce, 22 in statistical and geographical history, 9 in public health, 4 in fine arts, and 4 in various departments; altogether 160 prizes, including the foundations.

The section relating to chemical industry is divided into 14 sub-sections, in each of which several problems are presented for solution. The sub-sections are:—theoretical work, mordants, colours, fixation of colours, arcometry, drugs, bleaching, printing, decomposition of mordants, and processes of desiccation, steaming, engraving, actinometry, electricity, general.

In the mechanical section there are nine sub-divisions: construction of buildings, steam boilers, motors, and transmission, spinning, weaving, bleaching, printing, dyeing and dressing, distribution of water, electricity, gas-lighting, accidents from machinery (prevention of).

For the special problems which are set and other details connected with them, the programme, which can be obtained, on application from the General Secretary of the Industrial Society, must be consulted.—J. S.

THE FRANKLIN INSTITUTE REWARDS for MERITORIOUS DISCOVERIES AND INVENTIONS. Pamphlet, 3 pages.

THE Franklin Institute of the State of Pennsylvania, U.S.A., may grant, or recommend the grant of, the following medals for discoveries and inventions which contribute to the promotion of the arts and manufactures.

The *Elliot-Cresson Medal* (Gold) may be granted for some discovery in the arts and sciences, or for the invention or improvement of some useful machine, or for some new process, or combination of materials in manufactures, or for ingenuity, skill, or perfection, in workmanship.

The *John Scott Legacy, Premium, and Medal* (20 dollars and a bronze medal) is devoted to rewarding ingenious men and women who make useful inventions. This prize is awarded by the Board of Directors of City Trusts, but the nomination is made by the above institute.

The *Edward Longstreth Medal of Merit* (silver) may be awarded for a useful invention, an important discovery, and for meritorious work in, or contributions to, science or the industrial arts.

The secretary of the institute furnishes full particulars to those who wish their inventions and discoveries investigated with a view to obtaining the above medals.—J. S.

## GUTTA PERCHA.

The Société d'Encouragement pour l'Industrie Nationale is offering a prize of 120*l.* to anyone who will devise a substance capable of completely replacing gutta-percha in one at least of its principal uses, or for a work contributing to the increased production and better exploitation of this gum.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### UNITED STATES.

##### Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the Custom authorities in that country.

- (1.) Crystallising dishes made of very thin Bohemian glass and used for crystallising salts, chiefly in laboratories;
- (2.) Glass beakers or dishes with glass covers, used exclusively for growing bacilli germs therein; and
- (3.) Glass mortars and pestles, such as are chiefly used in laboratories, are dutiable at 45 per cent. *ad val.* under paragraph 107.

#### CHILI.

##### Exemption from Duty of Cyanide of Potassium.

Mr. J. G. Kennedy, Her Majesty's Minister at Santiago, in a despatch to the Foreign Office, dated the 2nd November, encloses copy with translation of a decree published in the *Official Gazette* declaring that cyanide of potassium and other similar substances may be imported duty free. A Bill, granting the above exemptions, was quickly passed through Congress and was framed on the petition of the representative of the Capell Gold Extracting Company, as an encouragement to gold mining in Chili.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### NEW PATENT LAW IN AUSTRIA-HUNGARY.

Mr. P. von Schöller, Her Majesty's Consul-General at Vienna, in a report to the Foreign Office, dated the 29th December, transmits the following summary of alterations recently made in the patent law of Austria-Hungary:—

A new patent law has been promulgated, coming into force on 1st day of January 1894.

In accordance with the stipulations of this new law the joint grant of patents in both sections of the monarchy is done away with, and in future new patents will be granted both in Austria and in Hungary independently.

Patents hitherto granted remain in force.

Commencing January 1st next, patents obtained in Austria are valid only in the provinces represented in the Austrian "Reichsrath."

For the granting of patents there need only be paid the patent tax, without any fee for registration.

The patent tax amounts to 21 florins for each year during the first five years, rising gradually to 105 florins in the 15th year.

Patents obtained in Austria enjoy the like priority in Hungary if the application for the grant of the patent there is made there within 90 days from the date of obtaining the said patent for Austria. This stipulation refers also *vice versa* to patents granted in Hungary.

The period of validity of the patent must be the same in both sections of the monarchy.

Patents from foreign applicants must, commencing January 1st, 1894, be applied for in Austria independently, the same as will be the case with home applicants.

Everything relating to special rights granted to foreigners in consequence of State treaties is in no way modified.—*Board of Trade Journal.*

### GENERAL TRADE NOTES.

#### GERMAN PRODUCTION OF ZINC.

The following note with reference to the production of zinc in Germany is contained in a recent issue of *Kuhlou's*:—

Germany produces more zinc than any other country in the world; the exportation of zinc is accordingly very heavy, amounting to 28,000 tons, against an importation of not quite 9,000 tons. The main zinc-production district is in Upper Silesia, where the metal is made from calamine, and also more and more from zinc blende, by distillation. The smelting of zinc blende has led here, as in other places, to the establishment of very perfect arrangements for utilising and preventing the deleterious effects of the sulphurous acid generated in the roasting of the ore. In Germany, in 1890, 139,000 tons of zinc were smelted, in which work 6,271 men were employed. The value of the output was 62,000,000 marks (15,500,000 dols. approx.), of which 64 per cent. was produced in Upper Silesia, 20 per cent. in the Arnburg district, and the remainder in the Government districts of Düsseldorf and Aachen (Aix-la-Chapelle), and the kingdom of Saxony. The ore in the western parts of the country is in the main zinc blende.

The smelting of zinc is made very difficult, in most localities, by the presence of other metals in the ore. However, by a careful preparation of the ores and purification of the zinc obtained, this difficulty has been overcome. By the use of regenerative gas, heating furnaces, and well-adapted condensers the cost of production has been reduced and loss of metal prevented. With the smelting of zinc a small production of cadmium is connected.

#### DEPRESSION IN THE GERMAN CHEMICAL INDUSTRY.

The *Moniteur Officiel du Commerce* for the 7th December quotes an article from the *Kölnische Zeitung* in confirmation of the bad state of the chemical products industry in Germany and other countries, and in view of the very embarrassed condition of affairs in the principal industrial countries, no other result, it is stated, could very well be expected.

Firstly, as regards America, business in general, but in particular the textile industry, has suffered by reason of the uncertainty as regards the action of the legislature. The export figures published by the different American consulates in Germany show a great diminution; such is particularly the case for the chemical products industry, as may be seen from recent reports by the American consuls at Frankfurt-on-the-Maine and Mannheim. The large factories of chemical products have, as is well known, as their chief customers the weaving works and, more particularly, the dye works and printing works, &c., and when these are affected the chemical products industry sees its principal market closed, and there is no doubt this is precisely what is happening now.

What has been said about America might be urged with stronger reason about England; the great export industry which, in order to impart the latest improvements to manufactured products of all imaginable kinds, uses large quantities of German chemical products, has been considerably affected by the monetary condition of India, by the situation of America, and, in an equal degree, by the serious strikes that have taken place in the coal trade. With respect to Russia, the door is closed, and that country is at present supplied by the large factories of Bâle. The Swiss factories also produce all the patented specialities of the large German companies.

By reason of a general depression of business and a commercial crisis such as exist at present, the chemical industry, as one of the most important industries of the Empire of Germany, must suffer. The reason of such a temporary stagnation in the export of products is extremely difficult to discover, and it is impossible to express an opinion on the subject of the influence exercised by the present state of affairs on the annual yields of the large joint-stock companies. These large establishments have, in fact, many specialities which secure them good returns;

they are well managed in every way and provided with sufficient capital, so that a temporary depression in trade does not produce essential changes in the producing power of these establishments. By reason of the critical condition of business and the difficulty in finding markets, competition has become keener in connection with a reduction in prices. Some factories of chemical products have much difficulty in keeping in full work; they seek to attain this end by offering their goods at a very cheap rate. Prices for most of the principal goods are extremely depressed. The consumption of pharmaceutical products has also somewhat fallen off.

#### LUCIFER MATCH WORKS.

##### *Report of the Committee of Inquiry, October 1893.*

The committee have been unable to trace any cases of necrosis since the special rules were established, beyond the two which have occurred in the factory of Messrs. Bryant and May, yet they are of opinion that danger from that disease exists to all workers where white or yellow phosphorus is used. The committee approve the special rules already in force, but suggest some alterations and addition, chiefly in regard to better ventilation and periodical medical examinations.

Persons are not to be employed in galleries above departments where fumes may rise; and the adoption of means, whereby matches becoming ignited in the boxing departments may be rapidly extinguished, is recommended.

The proposed new rules are then set forth.

#### MANUFACTURE OF CHINA AND EARTHENWARE.

##### *Report of Committee appointed to Inquire into the Injurious Conditions of the Manufacture, and the Proposed Remedies, July 1893.*

The committee were instructed "to make inquiry into the conditions under which the manufacture of pottery is carried on, with the object of diminishing any proved ill-effects in the health of the workpeople engaged therein."

The central town of "the Potteries," Stoke-on-Trent, was selected as the centre of the inquiry, four-fifths of those employed in this industry being employed in and around this centre.

In regard to the medical aspect of the question, it is considered beyond dispute that the potter's occupation is injurious to health and life. The ill-effects are referable to two chief causes—dust and lead poisoning. The former pervades all operations of the industry, while the latter prevails in the glazing and colouring processes after the ware leaves the hands of the potter properly so called. Firing the ware is also injurious, but to a less degree.

1. *Of the Dust of Potters' Clay and of Flint.*—This is noxious by inhalation into the lungs, acting as an irritant, setting up inflammation, and gradually consolidating the organ.

Statistics of life are then given, and the average age reached by potters is given as 48, as against 53 attained by non-potters. Fifty per cent. die of chest complaints, and 21 per cent. of pulmonary consumption. In the case of *pressers*, as distinguished from other potters, 54 per cent. die of chest diseases, and 29 per cent. of pulmonary consumption. The business of *pressers* is more dusty than that of other potters, and that of potters is more dusty than that of those following other avocations; hence the inference is that the inhalation of mineral dust is largely responsible for the mortality. Those exposed to flint dust, as compared with those inhaling clay dust, are very few in number. Those most exposed are the "china scourers,"—all females—who brush off the flint powder which adheres to china after its removal from the oven. Other sufferers are "china placers," "flint sifters," and the few who "flint" the ware before it is "placed." The scourers break down for the most part within a few years.

In all employments where dust is the active agent in inducing disease, the problem is how best to prevent its production, and when produced how to keep it from the workpeople. Its production may be stopped by cleanliness in work, avoiding the scattering of clay, arrangements for

removing waste, cleansing workshops, keeping shops cool so as to prevent the clay drying too rapidly, and by sprinkling the floors with water. Inhalation is best prevented by efficient ventilation and ample working space. Appliances for ventilation and exhaust draughts of air are needed for potters and flint-powder workers, and manufacturers are recommended to employ engineers to solve the problem according to the necessities of each occupation. All these improvements are without avail unless the workpeople co-operate. Hitherto such co-operation has been very imperfectly given.

*Lead Poisoning.*—The committee consider much of the mortality from lead poisoning to be avoidable, and that no rules can entirely obviate its effects, because so much depends upon the worker's personal care and cleanliness. There are several ways in which the poison can be introduced into the system. It is sufficiently proved that dust charged with lead finds its way usually through the stomach, and also, in all probability, through the respiratory passages. When in the form of moist glazes it also enters through the skin. It undoubtedly gains access into the body by—(a) eating food with unwashed hands or partaking of it in the rooms where lead is dealt with; (b) neglect of cleanliness of clothing; (c) allowing glaze and colours to drop about, become dry, and so form dust that gets inhaled; (d) holding the pencil used in painting in the mouth, as is often done by majolica painters; (e) rubbing the eyes with dirty hands; (f) near sightedness, causing the workers to be too close to their work; (g) some constitutional idiosyncrasy producing excessive susceptibility to the poison of lead. At the same time experience proves that many persons using lead glazes and colours work for a long series of years without manifest injury to their health. These are the careful ones. On the contrary many break down quickly; this is especially the case with young women and lads, with whom the influence of sex and age is a factor to be remembered, apart from that of careless habits. Another of some import is that of being ill-fed and debilitated. It is easy to tell at a glance between those likely to resist the action of the poison or to succumb to it by noting their personal cleanliness, their clothes, workplaces, and other surroundings.

Those employed in mixing glazes and colours, if taking ordinary precautions, seldom suffer. The sole use of "fritted" or fused lead has been advocated on the supposition that it is innocuous, and below will be found the results of the committee's investigations under this head.

Statistics prepared by Mr. Hordley, the assistant secretary of the North Staffordshire Infirmary, are then quoted, showing the comparative number of indoor patients treated in that institution in a series of years for lead poisoning among potters. Mr. E. J. Hammersley, secretary of the North Staffordshire Provident Society, has also prepared a table showing the ratio of lead cases among the members of the North Staffordshire Provident Society. In each case the tables show a striking diminution of the number of deaths from plumbism within recent years. It is, however, fair to note that the diminution of plumbism of late years is partly due to the reduced production of majolica ware during the last five years, and also to the enforcement of the order of the Secretary of State of December 1882, prohibiting the taking of meals in majolica painting shops. The higher rate of wages obtainable by dipping-house labour acts as an inducement to women and young persons to engage in it, and also to continue to work even when aware of its ill-effects upon their health; and it becomes a subject for serious consideration whether a periodical examination should not be insisted upon in the instance of all workers with lead, to be made by the certifying surgeons visiting the factories.

*Firing.*—The injurious conditions connected with the firing of the ware are flint dust, lead poison, heat from the furnaces, and the gases and dust evolved. Flint dust belongs to china placing only, the articles within the "saggars" being packed in it. Workers in this department also sift the powdered flint. The leading feature connected with firing is the heat, producing rheumatic affections, exhaustion, and bronchial attacks, and the ill-effects of the occupation

are augmented often by the carelessness of the workers. Further details as to this carelessness, combined with prejudice, in the matter of ventilation of workshops, are then cited.

#### *General Remarks and Suggestions.*

The committee does not think that there has been much improvement in the health of potters, except as to lead poisoning, in the course of the last 20 years. A general improvement in sanitary conditions has been counteracted by increased density of population and the consequent building over of the cottage gardens where the worker possessed a healthy source of interest outside his calling. Workers also live further from their work, and ride to it instead of walking; and the absence of exercise and healthy recreation produce resort to indoor entertainments, where the air is as vitiated as it is in the workshop.

The following suggestions are made:—(1) That no "ground laying" should be done in a room where other occupations are carried on; (2) flint-sifting should be so carried on that the dust is extracted by a fan; (3) shops in basements or below the surface of the ground should be forbidden; (4) lathe-treading should be disallowed for females under 16; (5) "wedging" of clay should not be done by boys under 13 or girls under 16; (6) no married woman should be employed where lead is used: it provokes miscarriage; (7) ware should not be kept on shelves above the heads of workers; and (8) hot closets in pressers' shops should have double doors. Special rules are then laid down, the enforcement of which, in the opinion of the committee, will greatly diminish the injurious effects of the various processes. These rules do not differ materially from those already in force.

The committee think power should be given to condemn such factories and parts of factories as are unfit for work.

With reference to the question of modifying manufacturing processes, the committee have considered the problem of modifying the method of glazing earthenware so as to dispense with the use of lead. At present the raw glaze in which the ware is dipped is a mixture in water of flint, stone, a "fritt" compound of borax and other ingredients, and white lead or red lead. White lead is known to be dangerous from its easy solubility, and two suggestions have been made with a view to meet the evil. One is to use leadless glazes only, which is incapable of universal application. The other is to fuzel all the lead required with the borax and other ingredients into a "fritt" or coarse glass, and to use lead only in that insoluble form. Some firms are now fritting all their lead, and claim it as an improvement; others regard it as impracticable. Mr. A. P. Laurie was therefore deputed to test the solubility of lead fritts in hydrochloric acid (a constituent of the gastric juice) and in bile. Bile was soon proved to be without action, but a solution containing 0.3 per cent. of HCl at 100° F. dissolved a considerable quantity of lead. Comparative experiments revealed that these fritts were better than raw lead, but differed in solubility according to composition. Mr. Laurie's final conclusion is that if the percentage of raw lead and the percentage of borax in a fritt do not amount, when added together, to more than 40, the fritt may be regarded as harmless; but if they amount to more than 40 it is probably too soluble to be safely used. The committee recommends manufacturers to continue their experiments in fritted lead, both with a view to obtaining a satisfactory glaze and to rendering the lead therein as insoluble as possible. In conclusion, the committee urges the desirability of providing mess-rooms for the workers, who, under the new rules, are prohibited from having meals in the work-rooms, and of instituting a periodical medical examination of workers in processes where lead is used or poisonous dust is generated.

#### REPORT OF THE CHEMICAL WORKS COMMITTEE OF INQUIRY, OCTOBER 1893.

The report of the committee appointed by the Home Secretary to inquire into the dangers to life, limb, and health attending employment in chemical works has just been issued. The scope of the inquiry included the conditions of labour in chemical works, the dangers to life

and health of the workpeople employed therein, and proposed remedies for these dangers. The exact questions which the committee was appointed to consider were:—

"(1.) How far the manufactures, as at present carried on in chemical works, injuriously affect the health of the workpeople; and how far the injurious effects depend upon the age and sex of the operatives.

"(2.) What means can be adopted to abate the injurious effects of the manufacture.

"(3.) What special regulations should be adopted to protect vats and other dangerous places and utensils used in the manufacture."

With regard to alkali works, the bleaching powder department is stated to be the most trying of all to those employed in chemical works, owing to the exposure to chlorine gas, under the system which generally prevails at present. In the "Weldon" chambers, which are most commonly used, a thick layer of lime, 4 in. to 6 in., is spread on the floor. The chambers are then closed, and strong chlorine gas is turned on, which is absorbed by the lime. At the end of about four days the gas is turned off, the free gas in the chamber is either drawn off by an exhaust or absorbed by a lime distributor, and the doors are opened. The men, about two hours after, enter to pack the powder. As soon as the powder is disturbed by the shovel it gives off chlorine gas, and no man could work in the chamber without some form of respirator. The packers, in order to work in the chambers, wear a respirator, commonly called a "muzzle." This consists of about 30 folds of flannel, damped and tied tightly over the mouth, with the nostrils free and resting on it. The men are obliged to inhale through the muzzle and exhale by means of the nostrils, otherwise they would be "gassed." The exertion of breathing through the thick folds of flannel shows itself by the red and puffed state of the men's faces, and profuse perspiration on coming out of the chambers, which they are obliged to do at intervals during their work. None but strong, healthy men could stand the work. In another process of making the bleaching powder the "Deacon" chambers are used. Though exposed to some gas, the packers at the Deacon chambers can use a very much smaller "muzzle," which is therefore not nearly so trying. In addition to these, mechanical means have been tried for the manufacture of bleaching powder which would obviate all exposure to the gas. The Hassen-clever process, by mechanical means (this Journal, 1889, 194), is said to be now successfully used in Germany. The committee express a strong hope that the old process may shortly be abolished for some mechanical process. Meanwhile they have suggested certain special rules to obviate in some degree the escape of gas for the benefit of those working in and around the chambers.

The manufacture of bichromate of potash or soda is practically in the hands of three Scottish firms. The committee found that almost all the men working where dust was prevalent had either perforation of the septum of the nose or had lost the septum altogether. Many of those employed suffer also from what are technically called "chrome holes" on hands and arms. These are caused by dust or liquor acting on broken skin, or by the handling of crystals. The committee strongly recommend the use of respirators where any dust arises and the use of gloves where crystals have to be handled. They are of opinion that the due observance of cleanliness on the part of the operatives would largely conduce to the prevention of the evils referred to.

Attention is called to the long hours of work in some departments of alkali works, and the adoption of the eight-hour shift is strongly advised. At the works of Messrs. Brunner, Mond, and Co., this system has been in force for some time, and has resulted in a great improvement in the condition of the health of the men employed. In 1889 before the eight-hour shifts were introduced, 10.12 per cent. of the employes were in the doctor's hands; in 1891 only 5.1 per cent. had to be attended. The committee say:—

"Messrs. Brunner, Mond, and Co. add that the cost of wages paid per ton of alkali produced by them is now no more than it was four years ago, in spite of the fact that

the men employed on shift work are paid the same wages for eight hours as they were formerly paid for twelve. This improvement they attribute partly to the improvements in the apparatus used, effected at considerable cost, and partly to the increased efficiency of the men, due to their better health and spirits."

As regards the question as to how far the injurious effects depend upon the age and sex of the operatives, the committee find that no females are employed in alkali works, and but few boys under 18 years, except in cooperages, plumbers' shops, box-making, &c. Moreover, their inquiries do not lead them to suppose that exceptional mortality, apart from accidents, exists in them. In conclusion, they believe that great good will ensue from the adoption of the proposed rules; and they strongly recommend that these be issued as soon as possible, looking at the unfortunate omission in the Factory Act of 1891, whereby all obligation to fence dangerous pots, pans, &c. was rescinded.

The two medical members of the committee submit a separate report dealing with the medical aspects of these questions considered more fully than is done in the general report.

A special set of rules for persons employed in caustic soda departments has been drawn up, and is recommended for adoption, as well as another set for bichromate works.

They are set forth below, and will be issued to the manufacturers, who will be allowed 21 days from the date of issue in which to make objections.

#### FACTORY AND WORKSHOP ACTS, 1878 TO 1891.

##### SPECIAL RULES.

##### *Chemical Works.*

I. In future every uncovered pot, pan, or other structure containing liquid of a dangerous character, shall be so constructed to be at least 3 ft. in height above the ground or platform. Those already in existence which are less than 3 ft. in height, or in cases where it is proved to the satisfaction of an inspector that a height of 3 ft. is impracticable, shall be securely fenced.

II. There shall be a clear space round such pots, pans, or other structures, or where any junction exists a barrier shall be so placed as to prevent passage.

III. Caustic pots shall be of such construction that there shall be no footing on the top or sides of the brickwork, and dome-shaped lids shall be used where possible.

IV. No unfenced planks or gangways shall be placed across pots, pans, or other structures containing liquid of a dangerous character. This rule shall not apply to black-ash vats where the vats themselves are otherwise securely fenced.

V. Suitable respirators shall be provided for the use of the workers in places where poisonous gases or injurious dust may be inhaled.

VI. The lighting of all dangerous places shall be made thoroughly efficient.

VII. Every place where caustic soda or caustic potash is manufactured shall be supplied with syringes or wash bottles, which shall be enclosed in covered boxes fixed in convenient places, in the proportion of one to every four caustic pots. They shall be of suitable form and size, and be kept full of clean water. Similar appliances shall be provided wherever, in the opinion of an inspector, they may be desirable.

VIII. Overalls, kept in a cleanly state, shall be provided for all workers in any room where chlorate of potash or other chlorate is ground. In every such room a bath shall be kept ready for immediate use.

In every chlorate mill, tallow or other solid lubricant shall be used instead of oil.

IX. Respirators charged with moist oxide of iron or other suitable substance shall be kept in accessible places ready for use in cases of emergency arising from sulphuretted hydrogen or other poisonous gases.

X. In salt-cake departments suitable measures shall be adopted by maintaining a proper draught and by other means to obviate the escape of low-level gases.

XI. Bleaching powder chambers, after the use thereof as far as may be practicable, been drawn off or absorbed by fresh lime, shall, before being opened, be tested by the standard recognised under the Alkali Act. Such tests shall be duly entered in a register kept for the purpose, which shall be produced to an inspector whenever called for.

All chambers shall be ventilated, as far as possible, when packing is being carried on, by means of open doors on opposite sides and openings in the roof so as to allow of a free current of air.

XII. In cases where the co-operation of the workers is required for carrying out the foregoing rules, and where such co-operation is not given, the workers shall be held liable in accordance with the Factory and Workshop Act, 1891, section 9, which runs as follows:—"If any person who is bound to observe any special rules established for any factory or workshop under this Act, acts in contravention of, or fails to comply with, any such special rule, he shall be liable on summary conviction to a fine not exceeding two pounds."

R. E. SPRAGUE ORAM,  
H.M. Chief Inspector of Factories.

#### FACTORY AND WORKSHOP ACTS, 1878 TO 1891.

##### SPECIAL RULES (CHEMICAL WORKS).

##### *Bichromate Works.*

I. In future every uncovered pot, pan, or other structure containing liquid of a dangerous character, shall be so constructed as to be at least 3 ft. in height above the ground or platform. Those already in existence, which are less than 3 ft. in height, or in cases where it is proved to the satisfaction of an inspector that a height of 3 ft. is impracticable, shall be securely fenced.

II. There shall be a clear space round such pots, pans, or other structures, or where any junction exists a barrier shall be so placed as to prevent passage.

III. No unfenced planks or gangways shall be placed across pots, pans, or other structures containing liquid of a dangerous character.

IV. Respirators suitable for protection of nostrils and mouth shall be provided where injurious dust or noxious fumes may be inhaled.

V. The lighting of all dangerous places shall be made thoroughly efficient.

VI. Inasmuch as dust is the principal cause of the various evil results to workers in chromium compounds, all due means shall be taken to limit in every way the formation of dust.

VII. Gloves of some waterproof material shall be provided for the use of workers who handle the crystals.

VIII. Sufficient lavatory accommodation, with hot and cold water, soap, nail brushes, and towels, shall be provided.

IX. In cases where the co-operation of the workers is required for carrying out the foregoing rules, and where such co-operation is not given, the workers shall be held liable in accordance with the Factory and Workshop Act 1891, section 9, which runs as follows:—"If any person who is bound to observe any special rules established for any factory or workshop under this Act, acts in contravention of, or fails to comply with, any such special rule, he shall be liable on summary conviction to a fine not exceeding two pounds."

R. E. SPRAGUE ORAM,  
H.M. Chief Inspector of Factories.

#### PROPOSED NEW SPECIAL RULES FOR CHEMICAL WORKS.

A meeting of the Chemical Section of the London Chamber of Commerce, was held at the office of the Chamber, in Eastcheap, on Friday, January 12, to consider the new special rules for chemical works proposed by the Home Office. Mr. Charles Wightman, Chairman of the Section, presided.

The CHAIRMAN said that he considered the rule demanding the covering of all vessels unworkable if strictly interpreted. It was not practicable to cover all vessels in which minor

chemical operations were carried on. He suggested that a resolution should be proposed agreeing to a recommendation of the sub-committee, that the authorities should be requested to alter Rule 1, so as to read:—

*"Every uncovered pot, pan, or other structure, containing liquid of a dangerous character, shall be so constructed as to be at least three feet in height above the ground or platform, or shall be securely fenced to the satisfaction of the inspector."*

Instead of as at present:—

*"Every uncovered pot, pan, or other structure, containing liquid of a dangerous character, shall be so constructed as to be at least three feet in height above the ground or platform. Those already in existence which are less than three feet in height, or in cases where it is proved to the satisfaction of an inspector that a height of three feet is impracticable, shall be securely fenced."*

This suggestion was unanimously carried, as was also one prefixing the word "uncovered" to the word "pots" in the second and fourth rules. A letter was then ordered to be written to the Home Office, expressing the Section's high appreciation of the rules, trusting that they would fulfil the objects aimed at, and suggesting the "very minor alterations" already described.—*Chemist and Druggist*.

#### THE PROPOSED NEW TARIFF LAW.

Since publishing the abstract of the new tariff Bill prepared by the Ways and Means Committee (this Journal, Dec. 1893, p. 1069), a few changes have been made by the committee. Those affecting the mineral industries are as follows:—

Magnesian firebrick, 1 dol. per ton. Pottery classification changed and rates made 35 and 40 per cent. Ferromanganese, from 22½ per cent. to 10 per cent.

Common black plate, from 35 per cent. *ad valorem* to a specific duty of nine tenths of a cent. Tin plate from an *ad valorem* duty of 40 per cent. to a specific duty of 1½ cents per pound, taking effect October 1st. Wire, from 30 to 35 per cent. Lead sheets, &c. made specific at 1½ cents per pound. Petroleum, crude or refined, is made free if the country producing it admits ours free.

The committee has also decided to recommend that the new law take effect June 1st, instead March 1st, as originally proposed.—*Engineering and Mining Journal*.

#### THE LEGALITY OF LABORATORY STILL.

The following case, which is of considerable interest, was heard recently at Paisley:—Zechariah John Heys, Zechariah Henry Heys, and Zechariah George Heys, trading under the firm of Zechariah Heys and Sons, makers of dyes, South Arthurlie, Barrhead, were charged at the instance of Mr. Peter Ryder, of the Inland Revenue Office, Paisley, with having contravened the second section of the Acts 9 and 10 Victoria, cap. 90, in so far as on 29th September in their premises at South Arthurlie, they, not being then and there persons known as regular makers of stills, nor being licensed distillers, rectifiers, or compounders of spirits, or vinegar makers, did keep and use a still without having taken out or having in force such license as was required under the said Act, whereby they were liable in a penalty of 50l. Respondents pleaded not guilty, and were defended by Mr. William Becket, writer, Glasgow, while Mr. Shearer appeared for the Inland Revenue authorities. Evidence was led, in the course of which it was stated that the still was used in the laboratory for concentrated methylated spirits so as to produce absolute alcohol, which was afterwards used for testing oils in order to determine the fatty matters in them. The still in question, it was also pointed out, was practically a toy, useful only for experiments in a laboratory. Mr. Shearer, on behalf of the Inland Revenue, said the prosecution was not for the purification of the methylated spirits, but for keeping the still without permission from the necessary authorities. The Bench held the charge proven, and imposed a modified penalty of 17.1s.—*Chemical Trade Journal*.

#### AN AUSTRALIAN COAL DISCOVERY.

An important discovery of coal, which is at the same time an instance of results confirming scientific observations, is noted in New South Wales, where coal of excellent quality has been struck under Port Jackson, which is the harbour of Sydney, at a depth of 2,929 ft. This is the second bore that has been put down in the same locality. The first reached a total depth of 3,095 ft., and at 2,901 ft. a "burnt" seam of coal about 8 ft. in thickness was pierced; but as it was known that some of the coal seams had been disturbed, and as the bore had proved the existence of a thick seam of coal, it was determined to sink a second in further search of the valuable deposit in the same locality, and the result has been, as stated, the discovery of a seam of good bituminous coal 10 ft. in thickness. The bore was made by an American diamond drill. The core of coal is 8 ft. long and 4 in. in diameter; the remainder of the coal was in dust driven up by the action of the water and will be analysed. The seam is known as the Bulli seam. The depth as determined in advance by Professor David was within 30 ft. of the actual depth, though the professor had nothing to guide him within 20 miles of the present bore, which is situated at Cremore Point on the north shore opposite, and about three miles from the principal wharfs. This coincidence must be considered largely as "luck," but at the same time it is a proof of the great regularity of the measures. Probably the condition of the coal as reported in the first bore-hole was due to careless boring grinding up the cores. The nearest worked coal-mine is some 40 miles south of Sydney by rail, and Newcastle, which is the principal coal port, is 70 miles north of Sydney. The bore was put down by the Sydney and Port Packing Coal Company, through the agency of the Government diamond drill, the engineer in charge being Mr. Hooper. The company received assistance from the prospecting fund voted by Parliament.—*Ibid*.

#### NATIVE ANTIMONY.

According to W. L. Watts, in the Eleventh Report of the State Mineralogist of California, which has just been published, a ledge of quartzite and porphyritic rock containing native antimony has been discovered on Erskine Creek, four miles south of Hot Springs, in Kern County. Two tons of metal were taken from a shaft 30 ft. deep and 1½ tons from a cut 8 ft. deep. The native antimony was found in nodular masses, coated with oxide of antimony and clay, which varied in weight from 1 oz. to 300 lb. The two openings from which ore was obtained were about 1,000 ft. apart, on the same ledge. There are many veins carrying sulphide of antimony in the neighbourhood of this ledge, particularly in a southerly direction therefrom, and numerous claims have been located, but are at present awaiting capital for development.—*Ibid*.

#### A NEW SOUTH WALES ANTIMONY MINE.

The Eleanora mine was discovered 13 years ago, and has been worked with varying fortunes until recently, when it has been placed on a substantial footing under charge of Mr. George Smith. At present, says the "Australian Mining Standard," the chief workings are near the main shaft, above the 400-ft. level north and south. Here the vein is on an average 7 ft. wide, carrying 11 dw. to 15 dw. of free gold per ton, and about 15 per cent. of antimony. After being hauled up the shaft the ore is screened; the coarse is hand-sorted and the fines are treated by a May's jigger. The antimony portion of the ore goes direct to the furnace, the remainder to the battery. At the south end of the mine a new main hauling shaft 12 × 4 ft. is being sunk to meet the 400-ft. level south from the No. 1 shaft. Good progress is being made with the work, and an adit is also being driven to drain the mine.

The crushing plant consists of a 25-head battery, which is hand-fed. When the ore has been crushed it passes over large baize tables on to three concentrators. The baize is washed every hour into bins. The material thus saved goes into two large amalgamating barrels, and after most of the gold has been caught, it again passes on to two small

separators. It is only six months since the concentrating plant was erected, yet 12,000 dols. worth of concentrates have been saved and sold to the Wallaroo Company. The tailings carry about 4 dwt. of gold, but these are all being saved for future treatment. As showing the tough nature of the ore, it may be mentioned that the 25-head of stamps only get through 140 tons per week, working full time.

The smelting plant consists of five reverberatory furnaces, four for treating the ore crude and one for reducing the oxide of antimony to white metal. The average production of antimony is over 10 tons per week. This is bagged and sold in London, fetching on an average 21*l.* per ton for crude, and 36*l.* for white metal. The average yield of gold is about 78 oz. per week, not including 3½ tons of concentrates of 9 oz. per ton. Mr. Smith estimates that there are 40,000 tons of tailings on the ground, containing 14,000 oz. of gold, and he is now working out a scheme for their treatment. When the electric power company commences operations it is the intention of the management of the Eleanora Company to erect a new 60-head battery with the best concentrating plant obtainable.—*Ibid.*

#### TEA-SEED OIL.

A writer in the *Indische Mercur* points out that *Camellia oleifera*, Abel, a plant closely allied to the tea-shrub yielding the leaves of commerce, is largely cultivated in China for the sake of the pale bland oil prepared from its seeds. These seeds contain a considerable proportion (10 to 44 per cent.) of oil of saponine, a toxic element, and their oil, unless refined, is, therefore, unsuited for eating. The pressed cakes, containing the bulk of the saponine, are used as a hair-wash, a fish-poison, and an insecticide. The seeds of the Japanese camellia (*C. japonica*) yield an oil which excels as a lubricant. Of tea oil proper (*i.e.*, oil from the seeds of *Camellia theifera*, Griff.), two varieties are recognised, *viz.*, the Chinese and the Assam oil. Chinese tea-seed oil is of the consistency of olive oil, pale yellow, and inodorous. The oil has a specific gravity of 0.917 to 0.927 at 15° C., is insoluble in alcohol, and congeals at -5° C. (?). It is edible, very suitable for soap manufacture, and forms a useful lubricant. Oil of Assam tea seed grown in Java has been investigated recently by Mr. L. van Itallie, city pharmacist, of Rotterdam. The oil is present in the husked seeds to the extent of about 20 per cent., and can be extracted by petroleum and ether. It has an acrid taste, a pale yellow colour, very thin consistency, a specific gravity of 0.920 at 15°, and congeals at -12°. Its iodine number (Hübl) is 88, and its saponification number 194. It contains 91.5 per cent. of fatty acids soluble in water. The chief constituents of the oil were palmitic acid (about 19 per cent.), liquefiable fatty acids (oleic and linoleic acids, about 72 per cent.), glycerin (about 8 per cent.), with traces of volatile fatty acids, lecithin, and phytosterin.

It is not at all unlikely that there may be a future for tea-seed oil in the European markets, but in that case it will be necessary to supply a better class of seed than that which was shown at the auctions. It is doubtful whether it would not be the better plan to send over the oil pressed in Ceylon or India. It appears that some of the merchants to whom samples of the tea-seed have been sent are of opinion that the oil obtained from it would find a ready sale in quantity, in London, at 20*l.* to 22*l.* per ton as a safe quotation. Planters are advised to crush 5 or 10 tons of seed and send the oil over to London, on trial, in packages not exceeding 10 cwt. each.—*Chemist and Druggist.*

#### THE MANUFACTURE OF ALUMINIUM.

U.S. Consular Reports, December 1893, 460.

On June 26, 1893, the Consuls at Birmingham, Bremen, Brussels, and St. Gall were instructed to make investigations and report upon the manufacture of aluminium in their respective districts.

Under date of July 25 the Consul at Bremen reported that the aluminium factory at Hamelingen, near Bremen, the only factory of the kind in his district, "ceased

operations some time ago," and now confines itself to the production of magnesium. The process at this factory for the manufacture of aluminium was too expensive to enable it to compete with factories employing the electric system.

The Consul at Brussels reports that aluminium is not manufactured in Belgium.

In 1888 there was organised in Europe a company or corporation called the Aluminium Industrie-Aetien-Gesellschaft (Aluminium Manufacturing Company). Its authorised capital was 2,000,000 dols., of which 800,000 dols. was paid up. Its purpose was the production of aluminium in large quantities and at low cost to the consumer. The caution of Schaffhausen, Switzerland, was induced by this company to grant it the privilege of drawing from the Rhine above the falls (known as the Rhine Falls), at the town of Neuchâtel, 20 cubic metres of water per second. In all the power thus obtained is equal to 1,000 horse-power. The method employed at Neuchâtel is the electric process of M. Héroult, a French inventor, who is a shareholder in the Neuchâtel company. This process is partly disclosed and can be described; but it also is partly undisclosed and kept a strict secret by the inventor.

What is disclosed of the process is substantially as follows:—Water from the Rhine sufficient to operate two turbines, or wheels, of 600 horse-power each, and a third of 300 horse-power, is conducted through large iron pipes. By means of the two wheels first named two large dynamos are set in motion, which generate an electric current of 14,000 amperes and 30 volts (1,500,000 Watts). This current is run over copper ropes to the electrodes of the apparatus in which the aluminium is produced, a sketch of which is given below. Loose smelted argil (clay), without any other mixture, is then brought into contact with the current at the electrodes. The positive electrode is of carbon (coal plates) and the negative of copper.

At the positive the oxygen of the argil combusts with the carbon and forms carbon oxide; at the negative the copper melted takes up from the argil the aluminium.

A is a large crucible. At *a, a', a'* copper pins admit the electric current to the crucible. B is the positive electrode, consisting of coal plates, joined together at the top by a frame and arm. A chain for raising and lowering the electrode is attached to this arm by a ring. A (the crucible) is covered with graphite plates (K) in which are holes for the admission of material to the crucible. These holes are closed by covers which can be removed to permit the escape of gases. At the beginning of an operation pieces of copper (which become the negative electrode) are put in the crucible. These are then caused to melt by lowering the positive electrode B and consequent production of a heavy current. The clay is next put in the crucible, and quickly melts. The aluminium (more or less alloyed) is drawn off through the aperture C.

By this process all the aluminium alloys can be produced, excepting such as involve metals which volatilize in the melting process.

The different trade qualities of the aluminium made by the Neuhausen company are as follows:—

Quality.	Aluminium.	Silicon.	Iron.
	Per Cent.	Per Cent.	Per Cent.
0.....	99.79	0.06	0.04
I.....	99.61	0.18	0.21
II.....	99.33	0.53	0.14
III.....	99.25	0.56	0.19
IV.....	99.14	0.58	0.28
V.....	96.79	1.84	1.37
VI.....	94.32	3.25	2.43
VII.....	92.84	3.82	3.34

Aluminium of qualities 0 and I can be forged in a hot or cold state; but aluminium of quality II can only be forged with great difficulty, as with 2 per cent. of silicon the metal becomes brittle.

Besides aluminium alloys, the Neuhausen concerns produces (as appears from the above table) practically pure aluminium. The details of the process by which this is done are not obtainable. They are the undisclosed part, of which mention has been made, of the method employed at Neuhausen. That the company in question is able to produce aluminium (both alloyed and pure) in such large quantities as it does and at such little cost is doubtless due in part to the exceptionally favourable arrangement by which its operating power is secured to it. It is due in part also to the experience and inventive genius of M. Héroult.

According to the last annual report of the directors of the Neuhausen company (that for 1892), the company had sold of their products—

Year.	Amount.	
	Francs.	Dols.
1890.....	493,000	98,600
1891.....	1,035,000	207,000
1892.....	2,100,000	420,000

Sales, it is stated, are no longer made by kilograms, but by carloads. It is also stated that in 1892 the dividend to the shareholders was 8 per cent.

But there have arisen in connection with the operation of the Neuhausen company some unexpected difficulties. Shortly after the factory was started the vineyards and vegetation in general of the country about the factory site began to wither. The neighbouring property-owners at once brought actions; but before they came to trial the factory-owners bought at high prices all the property affected. The factory was then enlarged, which served to spread the ill-effects to a territory beyond that which had been purchased.

Certain hotel-keepers then complained and asked that their property be bought also. On July 11th, 1893, at an extra session of the Regierungsrath (the cantonal legislature), before which the whole matter seems to have come, it was decided that the landowners complaining did so with just cause, and that the Neuhausen establishment must be closed, unless means could be devised to absorb or neutralise the gases to which it gave rise and which were destroying vegetation.

An expert—Professor Meister—has been set at work to consider the question of absorption. He states that he has been heretofore employed as an expert in this same line; that he knows the dangerous nature of the gases complained

of, hydrofluoric acid being the principal gas to which the harm done is to be attributed. He states further that, owing to the wide extent of territory involved, complete and effectual absorption will be both very difficult and expensive. He thinks, however, that with plenty of money the task can be achieved.

Meanwhile the matter rests. Should the Neuhausen company be unable, either from lack of financial or other means, to neutralise the injurious gases incident to the operation of their plant, it would seem that they must cease manufacturing.

A branch factory which was opened near that of Neuhausen, but in the canton of Zurich, has been subjected to litigation and is now closed. Whether the closing was because of the litigation or from other causes is not positively known.

#### NEW PROCESS FOR MAKING CITRIC ACID.

##### *U.S. Consular Reports, December 1893, 469.*

Dr. Carl Wehmer, a Hanoverian botanist, is said to have recently discovered that sugar solutions exposed to the action of certain microscopic fungi, the spores of which float in the atmosphere, become transformed into citric acid precisely identical with that extracted from the lemon.

The first experiments made to prepare artificially in this way citric acid are said to have given excellent results, 11 kilos. of sugar producing 6 kilos. of crystallised citric acid (this Journal, see p. ).

The new process has already been patented in several countries, including Italy; and at the factory of Thann, the distinguished chemist Scheurer-Kestner is now carrying on experiments with a view to applying the process on a large scale. Everything tends to show that this new process will assume great development and will make it possible to supply the trade with citric acid at a much lower cost than that actually ruling, and will in all probability supersede in a few years the present method of producing lemon juice and citrate of lime.

The article from which I quote closes by saying: "We make haste to notify our readers, so as to put lemon-growers on their guard, and to prevent new investments being made in this branch of agriculture, which must receive a great blow from this new method of preparing citric acid, and thereby sustain heavy losses."

To show what is meant by "heavy losses," I would refer to my report dated January 8, 1889. In the year 1887, from Messina alone, 4,438 pipes of 130 gallons of lemon juice (used to fix colours in calico printing), and valued at 635,834 dols., were exported. A large quantity of crystallised citric acid was also exported.

Unmerchandiseable lemons are turned to great account, in Sicily more particularly, by extracting the essence from the peel and by converting the juice into concentrated lemon juice. Should this resource now be taken from the Sicilian lemon-grower, he will indeed sustain a heavy loss.

While Florida and California lemon-growers will not be affected by this new discovery, should it ever prove all that is claimed for it, because their industry is still in its infancy, the question appears of sufficient interest to arrest attention.

#### NEW TABLE OILS IN GERMANY.

##### *U.S. Consular Reports, December 1883, 422.*

On account of the great expense and difficulty in procuring pure olive oil for table purposes, there have been many attempts made in Germany to produce from other substances that the olive an oil which, having all the qualities that recommend the olive oil, could be sold at a lower price.

In southern Germany for some years past oil has been produced from the beech-nut. It has given great satisfaction, but has not come into general use because the production has been small, and the oil has never been pushed on the market. One reason why more has not been done in the production of this beech-nut oil has been the great scarcity of the nut in certain years.

The beech-nut contains but 22·77 per cent. of oil, but when the nuts are plentiful, the ease with which they can be gathered, the fact that there is absolutely no other expense except the pressing, and the good prices that have been received for the oil, have made the production of the oil very profitable.

It is only of late that the seeds of the linden tree have been used for the production of oil. According to the report of Dr. C. Müller to the German Botanical Society, this oil has a number of excellent qualities, which would appear to make it certain that the linden seed will hereafter be considered one of the principal sources for obtaining table oil. The linden tree is a regular bearer, so that a large quantity of seed may be counted upon each autumn. The percentage of oil in the linden seed is given at 58. It is maintained that the oil has a peculiarly fine flavour—free from all bitter or aromatic taste—and that it has the appearance of olive oil. It belongs also to the oils which do not evaporate.

Oil made from linden seed will never become rancid. It has no tendency to oxygenate. It will stand a great degree of cold without freezing. Dr. Müller has exposed it to 3° F. below zero without being able to notice any change.

#### THE GRANTING OF PATENTS IN RUSSIA.

*Chem Ind.* 16, 472.

The Russian Board of Trade publishes the following declaration as to the manner of obtaining a patent in Russia, and as to the amount of the patent duties:—

Any person wishing to take out a patent can do so without the intermediation of an agent by presenting a petition to the Board of Trade. The petition to contain the name of the invention, the time for which the patent is required, as also the name, position, and address of the applicant. In the petition there must be given a clear and exact description of the invention, pointing out the novel points in the same (parts of the apparatus or a novel combination of known parts). Applications for patents for

engines, apparatus, or other articles have to be accompanied by a clear drawing, the individual parts lettered so as to correspond to the letters in the subject matter. In all cases where it is impossible to obtain a clear idea of the invention without a drawing, such drawing must be annexed. A petition is to be provided with two stamps each of 80 kopeks value, and, in addition, with a number of similar stamps corresponding to the number of the pages in the petition. At the same time the amount of the patent duty is to be paid in, either at the Board of Trade or at the nearest Government pay office for registration; the receipt for such payment must accompany the petition. The patent duty amounts to 90 roubles for three years, 150 roubles for five years, and 150 roubles for 10 years. When the petition is accepted the applicant receives a certificate to this effect, and the fact of the granting of the patent is published in certain specified newspapers.—H. A.

#### REPORT ON THE POSITION OF THE INDIA-RUBBER INDUSTRY IN 1892.

*E. Clouth, Chem. Ind.* 1893, 16, 193.

Owing to the steady rise in the price of Para-rubber, and to the high prices of cotton and linen yarns and fabrics on the one hand, and the downward tendency of the prices of the finished india-rubber articles on the other, the position of the india-rubber industry was no better in 1892 than in the previous year. Only in a few cases, such as the manufacture of bicycle tyres, and of driving belts from Balata rubber, which for this purpose appears to be especially suitable, were orders at remunerative prices forthcoming. The objectionable use of inferior raw material, the increase in the consumption of substitutes, and the working up of old, already vulcanised rubber (recovered rubber) were the inevitable consequence of this state of affairs, and led to a considerable deterioration in quality of the articles, against which consumers, to their own detriment, are still very indifferent.—C. O. W.

—W. MONTGOMERY & CO.'S CIRCULAR.

# THE ECONOMIC POSITION OF THE OPEN-HEARTH STEEL FURNACE.

H. H. Campbell. Paper Read before the English Congress at Chicago. *Engineering and Mining Journal*, December 23, 1893.

THE open-hearth furnace is a regenerative gas furnace in which pig iron, wrought iron, steel, or similar iron products are exposed to the direct action of the flame and converted into steel. As an outlet for the scrap ends and miscellaneous scrap from the steel mills of the country, the open-hearth furnace fills a position of general economic importance. More than this, it has been found peculiarly fitted for producing certain grades of structural and other steels, and furnaces have been operated where scrap was scarce and where it was necessary to use pig iron alone as the regular charge. Thus the process has been raised from a subsidiary to an independent position. In the field of structural work, as in other branches, the Bessemer converter is always a colossal rival. In the United States Bessemer linings are almost universally acid, and therefore in the following detailed comparison of the two processes it will be unnecessary to consider the metallurgical position of the basic converter or the applicability of its product to the stringent demands of modern engineering.

1. In making steel with the phosphorous from 0.06 to 0.10 per cent. the converter can turn out a product at less cost than the open hearth. For many purposes it answers well enough. In comparing it with open-hearth metal of exactly the same contents of carbon, silicon, manganese, phosphorus, sulphur, and copper, no marked difference can be detected by the ordinary methods of testing; but many engineers, after long experience with both metals under various trials and stresses, think that the Bessemer metal suffers a larger number of inexplicable breakages. Experiments on punched test-pieces indicate that this arises from its greater liability to crystallise under shearing stresses.

2. To make Bessemer steel with low phosphorus requires very careful selection of the raw material. If cupolas are used the pig iron will absorb both sulphur and phosphorus from the coke, and the percentage of these elements will be increased by the waste in the converter. The pig iron must therefore contain much less than the maximum of impurity allowed in the steel. It must also contain the requisite amount of silicon for successful blowing, and the scrap used in the vessel should be as pure as the iron. These conditions are not impossible or impracticable, but they enhance the cost of the product considerably and prevent the employment of pure Bessemer steel in competition with common open-hearth metal.

3. No solid fuel is used in the open-hearth furnace, and therefore phosphorus cannot be absorbed from it by the metal, while sulphur will not be unless the coal be unusually sulphurous. There is also more leeway in the selection of stock. In the acid-lined furnace, low- or high-silicon iron can be used, as well as washed pig, charcoal blooms, or basic scrap, while the smaller amount of oxidisable elements reduces the increase in the percentage of phosphorus and sulphur due to waste. In the basic furnaces the ability to remove both these objectionable impurities renders the question of stock a matter of secondary importance.

4. The conditions of Bessemer practice preclude a system of testing during the operation. The vessel may be turned down for a time, but a skull is likely to form on the lining where the metal lies, and this skull, if dissolved by a subsequent hotter charge, may appreciably affect the composition after a test has been taken. Moreover, the chilling of the charge during the testing is a matter of vital importance in the practical working of the mill. The fact must also be noted that the economy of the Bessemer process depends upon continuous and rapid running; any system of interrupted work is bound to raise the cost of the product.

5. The open hearth admits a system of testing without any correlated disadvantages. Such testing is necessarily crude, since the bath is continually changing under the action of the flame, and the results must be obtained quickly. The tests must also be taken before the addition of the recarburiser, and hence will be only relative. After

the addition of the recarburiser, the rapid oxidation of the manganese renders delays out of the question, but in spite of the limited opportunities the tests that can be made are of great value in controlling and regulating the composition of the charge.

6. Uniformity and homogeneity, therefore, are two of the most important factors in the comparison of the merits of the Bessemer and the open-hearth product, but unfortunately no conclusive testimony can be given to the skeptical or even the careful mind. No one conversant with the facts doubts that Bessemer heats can be made which are as homogeneous throughout as any open-hearth charge that was ever melted. No one doubts that in good practice the proportion of Bessemer heats which are not homogeneous is a small percentage of the whole number. But the question is not as to the homogeneity of ninety-nine heats, it is about the quality of the hundredth. And it is not one single test of this hundredth charge that is required but a large number of tests taken from all parts of the cast. One piece of steel differing radically from the rest wipes away all favourable arguments drawn from any number of other tests indicating homogeneity. The terms homogeneity and uniformity are often confounded. The first should mean the likeness of all parts of the same heat, and the second the likeness of one heat to another. It may be said that the second term includes the first, but this would imply a stretch of meaning, as by common acceptance it may be said that certain products are uniformly irregular. What is required in steel products is a combination of uniformity and homogeneity, and obviously no series of records, however long, can demonstrate the existence of this necessary combination, unless all heats have been thoroughly tested and have been found homogeneous.

In the case of low-carbon steels, the open-hearth possesses slightly better facilities for securing homogeneity and uniformity than the Bessemer. For high-carbon steels the conditions of manufacture make the hearth far superior. The metal in the converter is always blown until nearly all the carbon is eliminated, since the stopping of the blow at any definite intermediate point has proved impracticable. All the carbon content of the steel, therefore, must be added in the recarburiser, and absolutely perfect homogeneity can only be secured by absolutely perfect mixing. In the open hearth, on the other hand, the high-carbon steels are made by interrupting the process at the desired stage. It is plain that no mixing is required, so far as carbon is concerned, since about the same quantity of recarburiser will be used for a given manganese, whether high or low steel is being made.

The manganese in the recarburiser distributes itself very evenly under proper conditions. Some variations in physical properties will be caused by differences in finishing temperatures, and some by the fact that the test bars, not being machined, are not exactly round, and hence their area may not be accurately calculated, but the data will sufficiently indicate that the variations are not of practical importance.

The foregoing comparison of the open hearth and the converter may not be a convincing argument against Bessemer metal. It may justify engineers in using the cheap article in many structures, but it will also sustain the more cautious members of the profession who refuse to incur a known or probable risk. In adhering to the safest course, engineers are continually calling for a metal with lower phosphorous. The limit has been 0.10 per cent.; it is now 0.08; soon it will be 0.06; it should be 0.04. Every step in this direction means more work for the open hearth, and it means also the development of the basic furnace.

The stock required in acid work for a pure product is, and always must be, more expensive than for the common grades. The basic-lined furnace renders possible the elimination of the impurities. Like every new device, it has its censors. One of the commonest arguments against it is that good steel cannot be made from bad stock. This statement must be carefully qualified in speaking of the acid process, since the finest open-hearth and crucible-steels may be, and usually are, made from washed pig iron, puddled iron or charcoal blooms, all produced by the application of

a basic process to a more or less phosphoric iron. So far as the assertion is applied to the basic open-hearth process, it is unquestionably wrong; the first piece of good steel made from phosphoric iron relegated this doctrine to the realm of ignorant prejudice. Some engineers prefer not to employ basic metal rather than incur the least risk of unsatisfactory material from a new process. Against such reasoning little can be said, since it has already been admitted that Bessemer and open-hearth metals of the same composition may be unlike; but it is well to consider that a bad heat of steel made by the basic process may be due to ignorance and inexperience in new methods, while such an excuse is out of place when applied to the Bessemer practice, which has been developed for a generation.

### BOARD OF TRADE RETURNS.

#### SUMMARY OF IMPORTS.

Articles.	Year ending December 31st.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

24,406. W. P. Thompson.—From H. L. Fuge, Germany. Improvements in pressure regulators or reducers for gases, liquids, or the like. Complete Specification. December 19.

24,526. H. Reiser. Process and apparatus for cleansing filtering material. Complete Specification. December 20.

24,599. W. Crawford and J. Crawford. Improvements in vacuum apparatus for concentrating vegetable or other substances. December 21.

24,761. The Manchester Oxygen (Brin's Patent) Company, Limited, and W. M. Jackson. Improvements in means for utilising the pressure in cylinders or reservoirs containing compressed gases, and in the application and use of such gases. December 23.

25,011. B. E. R. Newlands. Improvements in apparatus for conveying substances and subjecting them to the action of gases or vapours or air currents, applicable also for drying, heating, cooling, or sifting substances, and for analogous uses. December 29.

1894.

24. J. B. Hilliard. Preventing gases from intermingling while passing through liquids. January 1.

58. A. W. T. Hüllsner and F. W. P. Röhrig. Improvements relating to the process and means for clarifying and filtering liquids. January 1.

70. G. Frère and M. Meslans. Improvements in the method of and apparatus of determining the density of gases. Complete Specification. Filed January 1. Date applied for 30th May 1893, being date of application in France.

232. J. Shenton. Improvements in the combustion chambers of puddling, mill, chemical, and other furnaces. January 4.

358. J. B. Allott. Improvements in drying and evaporating at low temperatures, and apparatus therefor. January 6.

575. A. L. G. Dehne. Improvements in filter presses. January 10.

659. L. Rusden and R. Eeles. Improvements in apparatus for the application of liquid fuel to furnaces. January 11.

697. H. M. Carroll and G. Hill. Improvements in stoking mechanism for gas retorts. January 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1893.

1780. H. J. E. Jensen. Improvements in and relating to filtering apparatus. January 10.

4076. J. J. Meldrum and T. F. Meldrum. Improvements in or connected with gas producers. December 30.

4112. E. L. Pease. An improvement in the construction of gas washers and ammonia stills. December 30.

5847. C. Sachs. Improvements in and relating to freezing or refrigerating apparatus. December 30.

15,484. E. A. Fehling and A. Steinbart. Improvements in and relating to pyrometers. December 27.

19,750. J. H. W. Ortmann and C. W. C. Herbst. An improved apparatus for sterilising or disinfecting liquids. December 27.

21,858. G. E. O. Lange. Improvements in apparatus for cooling milk and other fluids. December 27.

22,327. J. Bradbury. See Class VII.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

24,112. T. de Zebrowski. Improved process for the solidification of petroleum and apparatus therefor. December 19.

24,422. E. E. Dulier. An improvement in apparatus for destroying smoke. December 19.

24,431. R. Fegan. Improvements in the manufacture of coal briquettes. December 19.

24,432. R. Fegan. Improvements in the manufacture of briquettes from coal-dust or small coal. December 19.

24,524. S. Trivick, C. J. Head and A. Head. New or improved method of treating coke to render same more highly combustible. December 20.

24,603. R. F. English. An improvement in coal briquettes. December 21.

24,632. A. Farinetti and F. F. E. Heyse. A new or improved process for utilising asbestos for vaporising liquids and for distilling and producing gas from mineral oils. December 21.

24,826. J. Blum. Process of and apparatus for the conversion of carbonaceous matter into permanent gas practically free from nitrogen, for heating and illuminating purposes. December 27.

24,856. J. Young. Improvements in obtaining cyanides and ammonia direct from the air or other gases containing nitrogen. December 27.

24,955. B. J. B. Mills.—From La Compagnie Internationale pour l'Exploitation des procédés A. Seigle, France. See Class XII.

1894.

68. F. W. Clark. Improvements relating to the manufacture of gas for illuminating, heating, and other purposes, and to apparatus therefor. January 1.

81. F. Kempster. An apparatus for the utilisation of mineral oils for heating purposes. Complete Specification. January 2.

120. W. B. Fitch. Improvements in candles. January 2.

185. A. McLean. An improved mode of treating peat. January 3.

281. J. Murrie. An improved fuel economiser. January 5.

297. W. Steers. Improvements in fluid fuel injectors. January 5.

534. I. Carr. Improvements in or connected with the manufacture of illuminating gas. January 10.

647. T. Archer. An improved manufacture of fuel. January 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4022. F. Siemens. A process and apparatus for converting hydrocarbons into combustible gas. December 27.

21,707. E. Andreoli. Production of ozone and luminosity by electrical means. December 30.

22,159. C. Bolle.—From J. L. S. Joly. Improvement in the manufacture of candles. December 27.

22,396. R. Langhans. Improvements in the manufacture of incandescent bodies for incandescent gas lighting. December 27.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

## APPLICATION.

1894.

736. J. H. W. Stringfellow. Improvements in the treatment of tar, and in obtaining useful products therefrom. January 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1892.

21,343. W. J. Wisse and A. Schneller. New or improved treatment of hydro-carbons (or of analogous substances composed mainly of hydrogen and carbon) to decompose them and obtain various products. December 20.

1893.

5284. J. Y. Johnson.—From F. von Heyden. Improvements in the manufacture of guaiacol. January 17.

## IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS.

24,365. P. R. J. Willis.—From W. J. Matheson, United States. A new process of making solid and friable colouring matters from logwood extract and other dye-wood extracts. December 18.

24,543. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture of colouring matters and of intermediate products related to the rhodamine series. December 19.

24,713. S. Pitt.—From L. Cassella and Co., Germany. The production of  $\alpha_1$ ,  $\alpha_4$  dioxynaphthalene,  $\alpha_2$   $\beta_1$  disulpho acid, and azo dyestuffs deriving therefrom. December 22.

24,714. S. Pitt.—From L. Cassella and Co., Germany. The production of azo dye-stuffs derived from  $\alpha_1$ ,  $\alpha_4$  azimidonaphthalene. December 22.

24,715. S. Pitt.—From L. Cassella and Co., Germany. The production of dyestuffs from di-azo safranines and amidonaphtholes. December 22.

24,802. J. C. L. Durand, D. E. Inguenin, and A. J. J. d'Andiran. Manufacture of new colouring matters. Filed December 23. Complete Specification. Date applied for July 4, 1893, being date of application in France.

24,870. C. Dreyfus. The manufacture and production of new colouring matters. December 27.

24,888. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of diaceto compounds or analogous disubstituted acid, derivatives of amines, or substituted amines. December 27.

25,012. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. See Class VI.

25,074. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of sulpho acids of the naphthalene series derived from naphthalene  $\beta_1$   $\beta_3$  disulpho acid or naphthalene  $\beta_2$   $\beta_3$  disulpho acid. December 30.

1894.

77. D. M. Murrow and A. Taylor. Improvements in inks, dyes, and the like. January 2.

406. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brüning, Germany. Improvements in the production of sulphurous aromatic bases and of their sulphonic acids. January 8.

407. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brüning, Germany. See Class VI.

515. J. Y. Johnson.—From Kalle and Co., Germany. Improvements in and relating to the manufacture of azo dye-stuffs. January 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

3495. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of alkylated hydroxynaphthalene sulphonic acids and colouring matters therefrom. December 27.

4612. S. Pitt. From L. Cassella and Co. The production on the fibre by the aid of *p*-amido-diphenylamine of dyestuffs fast to light and washing. January 10.

4613. S. Pitt. from L. Cassella and Co. Improvements in the production of diamidonaphthalene sulpho-acid and amido-naphthol sulpho-acid, and colouring matters therefrom. January 10.

5039. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Improved manufacture of colouring matters. January 10.

5316. J. Hickisson. Improvements in the manufacture of coloured marking inks and marking ink pencils. January 17.

5320. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the manufacture of piperazine and its salts. January 17.

5407. S. Pitt. From L. Cassella and Co. The production of new disazo colouring matters. January 17.

7014. H. Kysow. A liquid blue for laundry purposes. January 10.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

## APPLICATIONS.

24,638. Comte H. de Chardonnet. Improvements in the manufacture of artificial silk. December 21.

24,758. W. Barraclough and B. Barraclough. An improved textile fabric. December 23.

24,769. J. H. Openshaw. Improvements in the manufacture of cloths known as cotton cords. December 23.

24,904. P. P. Craven. Improved process and machinery for glazing, polishing, and finishing textile fabrics. December 27.

24,978. E. N. Molesworth-Hepworth. Improvements in spinning cotton and other fibrous substances, and in apparatus therefor. December 29.

1894.

72. J. Lowman. New or improved machinery or apparatus for facing or surfacing cotton or other textile fabrics. January 1.

810. A. F. B. Gomess. An improvement in the treatment of textile vegetable fibres. January 13.

#### COMPLETE SPECIFICATION ACCEPTED.

1892.

18,358. A. F. B. Gomess. A new or improved process for the treatment of textile vegetable fibres, and in apparatus connected therewith. January 17.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

#### APPLICATIONS.

25,012. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The production of azo-colours upon fibres. December 29.

1894.

98. A. H. Leggiff. Improvements in machines or apparatus for applying bronze or other powders to the surface of paper, cardboard, cloth, and such like. January 2.

266. G. Wilkie. Improvements in and relating to appliances for mordanting yarn and thread. January 5.

407. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of azo-colours on the fibre by coupling in vacuo. January 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

977. J. M. Collins. Improvements in machines for dyeing and scouring yarn. January 17.

2009. L. Lang. Improvements in or relating to calico printing. December 30.

2153. O. Ostersetzer. Improvements in printing and dyeing on fabrics. January 17.

3660. H. Ashwell. Improvements in or relating to vats or like vessels for dyeing or treating textile fabrics or garments. January 10.

4612. S. Pitt.—From L. Cassella and Co., Germany. See Class IV.

18,232. O. P. Amend. Improvements in the process of dyeing. December 30.

18,517. J. G. Haslam. Improvements in yarn dyeing machines. January 10.

20,257. E. Labhardt. Apparatus for dyeing and washing loose and spun wool, cotton, and such like material. January 17.

### VII.—ACIDS, ALKALIS, AND SALTS.

#### APPLICATIONS.

24,475. J. R. Wyld and N. Glendinning. Improvements in the treatment of hydrochloric acid for the production of chlorine. December 20.

24,563. M. N. D'Andria. Improvements in and connected with the manufacture of magnesium hydrate. December 21.

24,739. A. J. Boulton.—From S. C. Peuchen and P. Clarke, Canada. Improvements in the concentration or vaporisation of sulphuric and acetic acids and in apparatus therefor. Complete Specification. December 23.

24,856. J. Young. See Class II.

25,023. H. Gaskell, jun., V. C. Driffield, A. Carey, and F. W. Wright. Improvements in and connected with the manufacture of bleaching powder. December 29.

25,024. H. Gaskell, jun., and A. Carey. Improvements in or relating to the manufacture of chlorine. December 29.

1894.

60. I. Werlein. An improved method or process of hardening aluminous materials and the product obtained thereby. January 1.

231. H. R. Angel and W. Smethurst. Making carbonic acid gas of a purer and more economic nature than heretofore by the ordinary processes. January 4.

456. P. C. Choate. Improvements in the art of preparing solutions carrying salts of zinc. Complete Specification. January 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4342. M. N. d'Andria. See Class XIII.

4920. T. Parker and A. E. Robinson. Improvements in the utilisation of chlorides of sodium and potassium for the obtaining of useful products. January 17.

13,722. C. Kellner. Improvements in the manufacture of ammonia, sodium hydroxide, and chlorine, and in apparatus therefor. December 27.

13,928. A. Muller. A method of and apparatus for effecting the absorption of carbonic acid.

22,327. J. Bradbury. Improvements in apparatus and furnaces for concentrating sulphuric acid and other liquids. January 17.

### VIII.—GLASS, POTTERY, AND EARTHENWARE.

#### APPLICATION.

24,682. The Worcester Royal Porcelain Co., Ltd., E. P. Evans, A. Rushton, and H. Hawker. Improvements in the manufacture of pottery or earthenware. December 22.

#### COMPLETE SPECIFICATION ACCEPTED.

1893.

19,699. W. W. R. Nicholls and R. C. Daley.—From The Lansalson China Clay Co. An improved system and apparatus for removing impurities from and refining china clay. January 17.

# IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

24,343. M. Koenen. Improvements in the manufacture of concrete blocks, bodies, or structures, and in apparatus therefor. December 18.

24,360. H. Jassoy. An improved method of constructing pavement stones, pavements, landings, and the like. December 18.

24,424. O. Hetterich. An improved process for making wood incombustible. December 19.

24,659. A. Gilechrist. Rollers for indenting cement, granolithic, concrete, or other pavement cements in a semi liquid state. December 22.

24,813. F. F. Scruby and W. H. K. Bowley. A fireproof wall and ceiling covering or decoration. December 23.

25,070. A. J. Boulton.—From D. Belloc and E. Bénard, France. Improvements in the manufacture of cement. December 30.

1894.

15. J. Dougan, J. McMillan, and J. L. Crawford. Improvements in materials and methods for erecting buildings. January 1.

16. J. Walker and R. Peach. An improved cement. January 1.

475. G. W. A. Stein. Improved method of manufacturing hydraulic cement. Complete Specification. Filed, January 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4588. S. McDougall and R. Parry. Improvements in or relating to street pavements, floors, platforms, steps, or the like. December 30.

4737. L. Nathan. Improvements in the manufacture of artificial marble. January 10.

5132. J. Hill. Improvements in the utilisation in the manufacture of Portland cement, of precipitated carbonate of lime forming waste products from chemical works, and in apparatus for employment therein. January 17.

22,782. H. Behrens. Improvements in the manufacture of moulded blocks, slabs, and other articles for use as building materials from cement or other similar substance or composition, and in moulds for producing the same. January 17.

# X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

24,685. W. Wright. Improvement in metallic alloys. December 22.

24,704. D. W. Sugg. Improvements in the manufacture of alloys. December 22.

24,767. W. Jenks. Improvements in furnaces for annealing iron and steel sheets, and in other furnaces employed in the manufacture or treatment of iron and steel. December 23.

24,796. W. Hayward, sen. A new or improved process for recovering tin from tin waste, tinned iron, and steel, and enamel from waste enamelled iron and steel, and furnaces and appliances for the said process and for other purposes. December 23.

24,900. E. Weinberg, R. Carriek, and J. G. Johanson. Improvements in the elimination of the oxides of zinc, iron, and copper from cobalt-oxide, and apparatus therefor. December 27.

24,939. H. L. Sulman. Improvements in the treatment of gold ores. December 30.

25,033. W. Evans. Improvements in or connected with puddling furnaces. December 29.

25,071. A. Trug. Method and apparatus for extracting gold and silver from their ores by the combined action of amalgamation and centrifugal force. Complete Specification. December 30.

1894.

132. T. G. Hunter. An improved process of removing tin from tin scrap or tin-coated metal. Complete Specification. January 2.

328. J. Tinn. An improvement relating to apparatus for galvanising sheet iron and steel. January 6.

364. R. Pearson. An improvement in the process of extracting gold from ores. January 6.

427. G. Robson. Treatment of finely-divided substances, such as crushed ores, slime, tailings, and the like, for the separation and recovery of metals and compounds therefrom, and apparatus therefor. January 8.

437. R. Heathfield and W. S. Rawson. Coating metallic surfaces with zinc and alloys of zinc. January 8.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

572. B. D. Martin and N. Martin. Improvements in the process or method of casting chilled rolls. January 10.

2377. A. Allen, A. Bashforth, and H. Allen. A reheating furnace for steel and iron puddling, and other purposes. January 17.

4001. H. W. Hemingway. Improvements in the manufacture of oxide of iron and in means applicable for use in such manufacture. December 27.

4328. A. Longsdon.—From L. Grambow. A new or improved process for improving the quality of steel armour plates. December 27.

5327. T. M. Ash, H. W. Gill, and L. Green. An improved process for coating or plating non-metallic articles with metal. January 10.

10,096. E. de Pass.—From H. Thofehn. Improvements in the manufacture of metallic oxides and compounds. December 30.

16,180. L. V. J. Lynen. Process and apparatus for the extraction of zinc. January 10.

16,857. A. Raze. Process for avoiding or considerably diminishing the choking and contraction of the mouth of the retort in the manufacture of the "Thomas" steel. December 27.

22,461. J. Cox. A new or improved metallic alloy. December 27.

22,828. R. Haddan.—From B. Jones. Improvements in and relating to cores, moulds, and mould-facings for the manufacture of steel and other metallic castings. December 30.

23,431. C. Raleigh. Improved means applicable for use in extracting gold and silver from auriferous and argentiferous solutions. January 10.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

24,295. H. F. Hoveler. Improvements in elements for secondary and other electric batteries, and in the manufacture of same. December 18.

24,344. J. A. Kingdon. Improvements in dynamo electric machines. December 18.

24,353. C. K. Mills.—From C. J. Barbier, France. A new or improved preparation of active material for electric accumulators. December 18.

24,389. A. Lehmann. Improvements in electrode plates for secondary batteries. December 18.

24,417. J. B. Torres. Improvements in electric or galvanic batteries. December 19.

24,442. C. K. Mills.—From C. J. Barbier, France. A new or improved electrical accumulator plate. December 19.

24,871. H. T. Johnson. Improvements in dry batteries. Complete Specification. December 27.

1894.

482. H. C. L. Holden. Improvements in secondary batteries. January 8.

494. W. P. Thompson.—From C. L. Coffin, United States. Improvements in forges or furnaces for heating or working metals electrically. Complete Specification. January 9.

496. W. P. Thompson.—From C. L. Coffin, United States. Improvements in apparatus for heating or welding metals electrically. Complete Specification. January 9.

646. W. Walker, jun., F. R. Wilkins, and J. Lones. Improvements in primary voltaic batteries. January 11.

669. C. J. Wollaston. Improvements in electric batteries. January 11.

670. A. Philip. Improvements in the manufacture of electrodes and use of the same. January 11.

835. J. Hargreaves and T. Bird. Improvements in the construction of electrolytic apparatus, and in the application thereof in oxidising, chlorinating, and analogous processes. January 13.

836. J. Hargreaves and T. Bird. Improved means for obtaining metallic bases and their compounds by electrolysis. January 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1892.

18,039. J. Hargreaves and T. Bird. Improvements in electrolytic cells and diaphragms. January 17.

23,101b. C. A. J. H. Schroeder and H. E. R. Schroeder. New or improved galvanic batteries. December 27.

23,773. R. Niewerth. Improvements in electric smelting, and in furnaces therefor. December 27.

1893.

660. H. F. Kirkpatrick-Picard and E. Thame. An improved method of manufacture of elements or plates for secondary batteries. January 10.

2241. C. A. J. H. Schroeder and H. E. R. Schroeder. High-tension battery. December 27.

3734. A. Hough and O. March. Improvements in secondary battery plates or elements. December 27.

3743. E. H. Liveing. Improvements in the preparation of carbon electrodes for electrolytic operations. December 27.

3744. E. H. Liveing. Improvements in the construction of carbon electrodes. December 27.

4691. The Lithanode and General Electric Co., Ltd., and J. T. Niblett. Improvements in the manufacture and production of elements for secondary batteries. January 17.

6605. E. T. Parker. Improvements in diaphragms for use in electrolytic processes. January 17.

22,311. E. P. Usher. Improvements relating to storage batteries. December 30.

22,312. E. P. Usher. Improvements in storage batteries. December 30.

23,436. H. H. Lake. From The Union Chemical Co. Improvements in apparatus for electrolytically producing soda and chlorine. January 17.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

24,461. T. Cordewener and A. de Kunwald. See Class XVIII.—A.

24,556. J. V. Ruymbeke. Process of distilling glycerin, and of treating the residuum of such distillation. December 20.

24,724. V. Contant. A new washing powder or compound. Filed December 22. Date applied for June 28, 1893, being date of application in France.

24,955. B. J. B. Mills. From La Compagnie Internationale pour l'Exploitation des procédés A. Seigle, France. Improvements in the composition of oils for feeding vapour-burning lamps. December 28.

24,956. L. Hatschek. Improvements in the manufacture of disinfectant soap. December 28.

25,001. H. W. Taylor. An improved soap. December 29.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

3469. J. S. Fairfax.—From W. D. Field. Improvements in or relating to compounds of "blown" or aerated oils with pyroxyline. December 30.

5107. H. D. Morgan. Soap cooling frames. January 17.

20,413. H. J. Bull. An improved method or process and apparatus for deodorising oils and fats. January 17.

23,387. W. T. Forbes. Improvements in the process and apparatus for extracting oil and other solvent matters from fibrous plants and other materials. January 10.

23,398. A. J. Boulton.—From A. Gross. Improved manufacture of detergent for washing and cleansing dirty linen. January 10.

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

### APPLICATIONS.

24,356. H. H. Lake.—From A. C. Girard and E. A. G. Street, France. An improved manufacture of writing pencils. December 18.

24,485. E. Bayley. An improved liquid enamel or glass for laundry use. December 20.

24,695. C. U. King and R. V. Jellicoe. Improvements in materials or compounds adapted for use in varnishes as substitutes for india-rubber, gutta-percha, and like substances, and for other purposes, and the process for their production. December 22.

1894.

71. W. H. Hyatt. Improvements in the manufacture of paint. January 1.

166. O. Imray.—From J. Sachs, C. E. Meier, and M. Gerstendorfer, United States. Improvements in the manufacture of pigments. Complete Specification. January 3.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

2883. A. Macdonald. Improvements in the treatment of galena for the production of lead, lead sulphate, and lead oxide. January 17.

4342. M. N. d'Andria. Improvements in and relating to the manufacture of paints, sulphuric and sulphurous acid from proto-sulphate of Iron. December 30.

4870. A. P. Laurie. Improvements in the preparation of oxide of zinc pigments. January 17.

5316. J. Hiekisson. See Class IV.

5349. M. N. d'Andria. Improvements in the manufacture of red oxide paints. January 17.

9825. E. Edwards.—From J. W. Overton. An improved paint. December 27.

16,703. J. V. Walton. Improvements in apparatus employed in the manufacture of white lead. December 30.

17,142. L. Grote. Improvements in the manufacture of artificial stone preservative paint, and other analogous materials. January 10.

22,294. E. Waller. Improvements in the manufacture of white lead. December 27.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATIONS.

24,463. W. Zahn. Improvements in the art or process of tawing hides or skins. Complete Specification. December 19.

24,468. C. B. Dawney. An improvement in process for treating hides and skins for leather. December 20.

1894.

230. J. McNeill. An improved glutinous composition, applicable to leather, gutta-percha, and cotton belts. January 4.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

4274. W. Becker. An improved process to make leather soft, durable, and waterproof. December 30.

## XV.—AGRICULTURE AND MANURES.

## APPLICATIONS.

24,465. A. R. O. Pieper. Improvements relating to the manufacture of artificial manure. December 19.

1894.

792. M. C. Gunster. Improvements in the manufacture of manure and fertiliser. January 13.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

24,718. S. Touyarou. Improvements in the manufacture of sugar and in machinery therefor. December 22.

24,742. E. Shaw. Improved method of and apparatus for boiling sugar and glucose either separately or mixed. December 23.

1894.

136. H. H. Lake.—From P. H. V. Weyde and O. Lugo, United States. Improvements in the manufacture of sugar. Complete Specification. January 2.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

5617. H. H. Lake.—From W. Angele. Improvements relating to the manufacture of soluble starch. December 27.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

24,548. R. Genge. Improvements in the preparation of malt and in apparatus therefor. December 20.

24,708. F. W. Golby.—From P. Condamin, France. A process for the crystallisation of liqueurs. December 22.

24,880. O. Imray.—From L. Genes, France. Improvements in the manufacture of yeast and alcohol. December 27.

25,052. S. H. Sheldrake. An improved process for the preparation of ale and stout. December 30.

1894.

54. C. E. Ramspott. An improved process for the production of a non-alcoholic beverage. January 1.

507. T. Chandler. A new or improved malt product and process for manufacturing same. January 9.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

228. A. Blake. An improvement relating to the process of malting grain. January 10.

# XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

### A.—Chemistry of Foods.

24,461. T. Cordewener and A. de Kunwald. Improvements in and in apparatus for the manufacture of margarine and alimentary fat. Complete Specification. December 19.

24,970. M. Watson. Improvements in cereal leguminous or other vegetable foods. December 28.

### B.—Sanitary Chemistry.

25,040. H. B. Sharp and J. B. Petrie. Improvements in the preparation of compositions adapted for use in the treatment of sewage and foul waters. December 30.

### C.—Disinfectants.

24,531. S. Pitt.—From the Chemische Fabrik auf Actien vorm. E. Schering, Germany. An improved antiseptic disinfectant or deodorant. December 20.

24,709. S. F. Kattenhoy. Apparatus for the production of ozone from phosphorons for disinfecting purposes. Complete Specification. December 22.

24,956. L. Hatscheck. See Class XII.

1894.

147. C. G. Moor. An improved disinfectant. January 3.

## COMPLETE SPECIFICATIONS ACCEPTED.

### A.—Chemistry of Foods.

1893.

4486. W. Clark. Improvements in fluid meats and the process of manufacturing the same. December 30.

4487. W. Clark. Improvements in food preparations and in their manufacture. December 30.

12,617. H. W. Hart. Improved method of treating coffee berries for the extraction and production of their food and health (dietetic) giving constituents. January 17.

21,448. W. B. Walters. A mixing or churning apparatus for use in making butter and condensed milk. December 27.

22,287. M. Kirchberger.—From Ban Heng Hin and Co. Improvements in the treatment of pepper. December 27.

## XIX.—PAPER, PASTEBOARD, Etc.

### APPLICATIONS.

24,503. J. Y. Johnson.—From P. Sohège, France. Improvements in the manufacture of cellulose pulp. December 20.

24,521. C. Beadle. A process for treating paper so as to provide against falsification of documents. December 20.

24,652. W. M. C. Callender. The manufacture of a new material designed to serve as a substitute for bone or celluloid. Complete Specification. December 21.

24,669. J. Craig. Improvements in machinery or apparatus for manufacturing paper. December 22.

1894.

109. C. F. Cross. Treatment of wood for the manufacture of cellulose and other products. January 8.

824. W. White. An improved method of preparing pigment paper for photographic printing. Complete Specification. January 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1892.

23,603. W. Ibbotson. Coating or covering paper with aluminium and its alloys. December 27.

1893.

22,415. D. Westad. Improvements in machines for making millboard or paste-board from wood-pulp. December 27.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

### APPLICATIONS.

24,459. S. Pitt.—From The Chemische Fabrik auf Actien vorm. E. Schering, Germany. Improvements in the manufacture of laevulose. December 19.

24,604. S. W. Wilkinson. Improvements in or applicable to aromatic hydrocarbons and their manufacture. December 21.

1894.

189. J. F. Challen. Orangine. January 3.

681. F. W. Warrick. An improvement in capsules of ferrous carbonate and ferrous phosphate. Complete Specification. January 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1892.

23,449. H. Byk. Improvements in the method of obtaining phenols and naphthols, commonly called "salols," from salicylic acid, &c. December 27.

1893.

4191. O. Imray.—From The Society of Chemical Industry in Basle. Manufacture of new pharmaceutical compounds. December 30.

12,617. H. W. Hart. See Class XVIII.—(A).

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

### APPLICATIONS.

24,487. A. Burchett. Improvements in photography. December 20.

24,963. J. Packham. Improvements in producing photographic prints. December 28.

25,002. M. Andresen. Improvements relating to the development of photographic pictures. December 29.

1894.

824. W. White. See Class XIX.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

24,425. H. Boyd. A new explosive. December 19.

1894.

601. H. V. Keeson. Improvements in percussion fuses for projectiles. January 11.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

22,384. R. C. Schupphaus. Improvements in methods of securing the chemical stability of nitro-compounds. December 27.

# THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—Vol. XLII.]

FEBRUARY 28, 1894.

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S. ....	1882—1883.
Walter Weldou, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond, F.R.S. ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.
E. Rider Cook ....	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S. ....	1891—1892.
Sir John Evans, K.C.B., F.R.S. ....	1892—1893.

## COUNCIL FOR YEAR ENDING JULY, 1894.

**President:** E. C. C. Stanford.

### Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	Dr. W. H. Perkin, F.R.S.
Horace T. Brown, F.R.S.	Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.
H. Brunner.	John Spiller.
Wm. Crowder.	Prof. T. E. Thorpe, F.R.S.
Sir John Evans, K.C.B., P.R.S.	Sir John Turney.
Dr. F. Hunter.	
E. K. Muspratt.	

### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
Prof. Frank Clowes, D.Sc.	John Pattinson.
Dr. C. Dreyfus.	Manning Prentice.
Thos. Fairley.	Boverton Redwood.
C. A. Fawsitt.	A. Gordon Salamon.
Prof. G. G. Henderson, D.Sc.	T. Tyrer.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

**General Secretary:** Charles G. Cresswell.

**Offices:** Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hunter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	C. Clarke Hutchinson.
Joseph Bernays, M.I.C.E.	Wm. Kellner, Ph.D.
H. Brunner.	Ludwig Mond, F.R.S.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
Sir John Evans, K.C.B., F.R.S.	H. R. Procter.
Percy Gilchrist, F.R.S.	Boverton Redwood.
John Heron.	John Spiller.
D. B. Hewitt, M.D.	Wm. Thorp.
David Howard.	Thomas Tyrer.
Prof. J. J. Hummel.

## NOTICES.

### ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Edinburgh in the month of July next. Full particulars will appear in a subsequent issue.

### BANKERS' ORDERS.

For the convenience of Members, the Treasurer has arranged with the Bankers of the Society that they shall collect subscriptions from Bankers in town and country; and Members, who have not already done so, are invited to fill up and sign the Banker's Order enclosed with the December number of the Journal, which should then be sent to the Honorary Treasurer, Mr. E. Rider Cook, East London Soap Works, Bow, E.

### PATENT LAW REVISION.

Discussions upon the proposed revision of the Patent Law have been held in all Sections of the Society.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

#### CANDIDATES FOR ELECTION AT COUNCIL MEETING. 23rd FEBRUARY 1894.

Ansbacher, Louis A., P.O. Box 1934, New York, U.S.A., colour manufacturer.

Buchan, Alex., 93, Malmesbury Road, Canning Town, E., chemist.

Coker, Ernest G., H.M. Patent Office, Chancery Lane, W.C., examiner of patents.

Cowburn, W. H., Hope House, Bignor Street, Cheetham Hill, Manchester, chemical merchant.

Dufton, Arthur, Technical College, Bradford, Yorks, teacher of chemistry and dyeing.

Fletcher, Ernest L., Grappeuhall, near Warrington, gas engineer.

Hadley, Walter S., Millersdale, Sutton, St. Helens, Lancashire, plate-glass maker.

Haynes, David O., P.O. Box 583, Detroit, Mich., U.S.A., proprietor of "Pharmaceutical Era."

Hepburn, J. G., Priory Works, Dartford, Kent, leather manufacturer.

Hills, Harold F., 149, Bow Road, London E., analytical chemist.

Jones, M. W., 50, Mayfield Road, Whalley Range, Manchester, chemist.

Knight, W. A., Sexey's Trade School, Bruton, Somerset, head master.

Krause, Dr. Albert H., 132, Woodland Avenue, Cleveland, Ohio, U.S.A., chemist, Grasselli Chemical Company.

Langen, H. G., Maschinenfabrik, Greveubroich, Germany, chemical engineer.

Leitch, Jno. W., Millsbridge Chemical Works, near Huddersfield, aniline dye manufacturer.

Loewenstein, Harry H., c/o The Lowe Bros. Co., Dayton, Ohio, U.S.A., chemist.

Louis, Henry, 20, Lancaster Road, Belsize Park, N.W., mining and metallurgical engineer.

McMullan, Chas., 20, Corn Market, Belfast, Ireland, soap works manager.

Maxwell, John, Solway Chemical Works, Sillioth, Cumberland, chemical mazure manufacturer.

Nuttall, Harry, c/o John A. Bremner and Co., Albert Street, St. Mary's, Manchester, oil manufacturer.

Picard, Hugh F. K., 59, Abbey Road, St. John's Wood, N.W., metallurgist.

Santer, Herbert, Albion Brewery, Caledonian Road, N., brewer.

Schidrowitz, Philip, 24, Chichester Street, Chester, research chemist.

Sohn, Chas. E., 25, Beverley Road, Anerley, S.E., analyst.

Waldman, Louis J., P.O. Box 162, Albany, N.Y., U.S.A., aniline dye manufacturer.

Watmough, Benj., 4, Ferneliffe Road, Bramley, near Leeds, analytical chemist.

Watson, Jas., Caldwell, South Shields, assistant manager of alkali works.

White, W. Gilchrist, Lamb-Roe, Whalley, Lancashire, calico printer's chemist.

Wotherspoon, Peter, 14, Prospect Terrace, Jarrow-on-Tyne, chemist.

#### CHANGES OF ADDRESS.

Abbott, John, 1/o London; 6, Chichester Terrace, Brighton.

Buchanan, Josh., 1/o Glasgow; c/o Randfontein G.M. Co., Box 73, Krugersdorp, S.A.R.

Corbould, W. H., 1/o South Australia; Coolgardie, West Australia.

Dixon, M. T., 1/o Brandling Park; 18, St. Thomas' Crescent, Newcastle-on-Tyne.

Dougall, Andrew, 1/o Fallowfield; 27, Beverley Road, Hull.

Ellis, C. J., 1/o Glasgow; c/o Mysore G.M. Co., Ltd., Oorgaum, Mysore, South India.

Field, C. H., 1/o Nottingham; Green Street Green, Orpington, Kent.

Fogg, Jas., 1/o Trinidad; c/o Mrs. Anderson, 22, Warwick Street, Glasgow, S.S.

Gibson, Dr. J., 1/o Harrington Gardens; 20, George Square, Edinburgh.

Harmon, L. E., 1/o New York; Clover Mills, Buffalo, N.Y., U.S.A.

Isaac, J. F. V., 1/o Putney; 114, Marine Parade, Glasgow.

Ivatts, Harold E., Journals to 203, Earlham Grove, Forest Gate, E.

Loewenthal, Dr. R., 1/o Schwerin; Steglitzerstrasse, Berlin, W.

Luthy, Otto, 1/o Barberton; 2336, Fairmount Avenue, Philadelphia, Pa., U.S.A.

McFarlane, R. F., 1/o Servia; 27, Cardigan Terrace, Heaton, Newcastle-on-Tyne.

Manu, Harold H., 1/o York; 5, Rue Rollin, Rue Monge, Paris.

Manning, Isaac H., 1/o Baltimore; Chapel Hill, N. Car., U.S.A.

Miller, Dr. A. K.; Journals to 111, Plymouth Grove, Manchester.

Miller, Geo., 1/o Widnes; Church Cottage, Halewood, Lancashire.

Nichols, J. A., 1/o Hurstfield; Stanley Mount, New Mills, Stockport.

Pedler, J. R., 1/o Dulwich; 47, Tregunter Road, South Kensington, S.W.

Phipson, Dr. T. L.; Journals to 8, Hotham Villas Road, Putney, S.W.

Pope, W. J., 1/o Hartismere Road; 16, Barclay Road, Waltham Green, S.W.

Preston, E. S., 1/o Plymouth; Easton, Weybridge, Surrey.

Quinn, J. Cardwell, 1/o Upper Thames Street; 503, Romford Road, Forest Gate, E.

Rayner, J. A. E., 1/o Ambleside; Grove House, Waver-tree, Liverpool.

Richardson, Clifford; Journals to Central Power Station, Washington, D.C., U.S.A.

Saniter, E. H.; Journals to 11, New Market Street, Wigan.

Towers, J. W., 1/o Widnes; Brantwood, Allerton, near Liverpool.

Tulloch, J., 1/o Jarrow; 11, Newton Terrace, Hebburn-on-Tyne.

Turgensen, Dr. Rolof, 1/o Offenbach; Smetanka 6, Weinberge, Prague, Austria.

Zinkeisen, Dr. W., 1/o Glasgow; 9, Campden Grove, Kensington, W.

#### RESIGNATIONS CANCELLED.

Leeds, Prof. Albert R., Stevens Institute of Technology, Hoboken, N.J., U.S.A.

Whitaker, Alf., Waltham, Horsforth, Leeds.

#### ERRATA IN LIST.

Larsen, J., should be spelt Larson, J.; address as before.

Rouillard, R. A. (wrongly spelt Romillard), 5, Dundonald Road, Wimbledon.

## Deaths.

Smith, Thos., Heriot Hill House, Edinburgh.

Solvay, Alf., 25, Rue du Prince Albert, Brussels. At Nice.

## London Section.

THE CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE, W.

Chairman: Wm. Thorp.

Vice-Chairman: W. Crowder.

### Committee:

E. J. Bevan.  
W. G. Blagden.  
C. C. Hutchinson.  
T. A. Lawson.  
R. Messel.  
B. E. R. Newlands.

Hon. Local Secretary: John Heron,  
74, North Side, Clapham Common, S.W.

### SESSION 1893-94.

#### REMAINING MEETINGS.

First Monday in each Month at 8 p.m.

March 5th:—

Admiral J. H. Selwyn. "The Zymean Metallurgy."  
Mr. F. Bale. "The Commercial Production of Chlorine by the Ammonia-Soda Process."  
Mr. F. H. Leeds, F.I.C., F.C.S. "Notes on Lithographic Varnish."

April 2nd:—

Mr. J. W. Lovibond. "Colour as a means of Quantitative Estimation."  
Mr. W. C. Young, F.I.C., F.C.S. "The Natural Diminution of the Dissolved Organic Matter in the Water of Rivers."  
Mr. H. Louis, A.R.S.M., F.I.C., F.G.S., &c. "Notes on an Improved Specific Gravity Bottle."

N.B.—Election of Officers and Five Members to the Local Committee.

Nominations must be signed by Ten Members and sent to the Hon. Local Secretary not later than Tuesday, March 20th. Members can only sign one nomination. (See By-Laws.)

April 16th (extra meeting).—Mr. H. de Mosenthal. "Gold Extraction Process."

May 7th:—

Mr. Claude Vautin. "The Commercial Electrolysis of Fused Salts."  
Messrs. W. H. Stanger, Memb. Inst. C.E., and Bertram Blount, F.I.C., F.C.S. "Testing of Hydraulic Cements."  
Mr. Oscar Guttmann, Assoc. M. Inst. C.E., F.I.C. "Manufacture of Smokeless Powder."

June 4th:—

Mr. W. G. Macmillan:  
(a.) "Experiments on the Strength of Leather."  
(b.) "Note on the Colour of Brass."  
Dr. P. Dvorkovitch. "Distillation of Peat."

Notes of the Meetings appear regularly in the Scientific Press.

Meeting held Monday, February 5th, 1894.

MR. WM. THORP IN THE CHAIR.

## THEORY OF DYEING. PART I. "INGRAIN COLOURS."

BY W. P. DREAPER, F.I.C., F.C.S.

**General Introduction.**—It was not until comparatively recent times, that chemists attempted to study and explain the very varied phenomena which make up what is termed "the practice of dyeing." In fact, until a large amount of close work had been done in physical and organic chemistry, the problem was an almost insurmountable one, and could not be attacked with much chance of success. Unfortunately, until late years, the part played by the fibre on which the colour is dyed and introduced, was to a

great extent ignored. Probably most investigators sided with those who favoured a more or less mechanical theory, being influenced, no doubt, by the more easily investigated problem of the part played by mordants, and other questions, which it is hardly necessary to go into on the present occasion. The introduction of "aniline" colours, and the tremendous impetus given to research in this direction from the year 1856, naturally kept research chemists who were interested in the matter, working at the chemistry of the dyes themselves.

However, the question gradually resolved itself into "Is the process of dyeing a purely chemical or mechanical one?" This question, in spite of a certain amount of work that has been done on the subject, has not yet been finally answered.

In taking into account any theory of dyeing, whether chemical or mechanical, there is one thing that must be considered. As the fibres are constituted, one must allow of two processes in the dyeing. Firstly, a process by which the dye is brought into contact with the general mass of the fibre, and then, in the case of a chemical theory, the reaction which takes place between the fibre and the dye. In all processes going under the name of dyeing, it is necessary to present the dye to the fibre in a suitable form. In simple dyeing this is nearly always brought about by dissolving the former in some convenient solvent, and then immersing the fibre in it, under certain conditions of temperature, concentration, &c.

The phenomenon of solid solution was first noticed by Van t'Hoff in 1890 (*Zeits. f. Phys. Chem.* 5, 322), and it was, I believe, first suggested by Otto N. Witt, in 1891 (*Färb. Zeit.* 1890-91), as an explanation of the process of dyeing. Certainly all the conditions necessary to this theory are present, and great attention has been lately paid to it.

On the other hand, Leo Vignon (*Comptes Rend.* 110, 286, 112, 623), E. Knecht (*J. Soc. D. and C.* 1889, 77), and others, have insisted, and brought forward results which tend to prove, that the process of dyeing is a purely chemical one. Knecht's results show that when silk, or wool, is dyed with basic colouring matters, the dye is decomposed, the base combining with the fibre, the acid remaining in solution. He says, in conclusion, "This affords an almost undeniable proof that, in those cases at least, the dyeing is not a mechanical absorption, but a strictly chemical one." He also noticed that the wool would only take up a certain maximum amount of colour.

According to this general view, silk and wool are probably amido-acids, which have the power of combining with either an acid or basic compound. Vignon, experimenting on cellulose, found that by introducing an amido group into the cellulose molecule (by treating with strong ammonia at a high temperature, and under pressure), the fibre then readily took up acid dyes. This result is interesting, and, although only what might be expected, shows that the above chemical theory may apply to silk or wool, as both of them contain nitrogen.

Richardson (this Journal, 1893, 426), in an interesting article, tends to show that the "mass formula"—

represents the silk molecule, and that the following graphic formula probably represents fibroin:—

$x$  representing a hydrocarbon residue. However, it will be generally acknowledged that a great deal more work will have to be done on the subject before the question is finally settled. A method of dyeing has lately been patented, based on this knowledge, azo dyes being directly produced by diazotising silk fibre and combining with suitable phenols and amines. I have prepared one or two samples in this manner, and, with apologies to the patentee, I now produce them for your inspection.

It is almost unnecessary to state that cellulose will not act in this manner, and from its constitution a theory which will satisfy the requirements of silk and wool dyeing will not be applicable to cotton, as will be seen from the

following formula of cellulose, as recently given by Messrs. Cross and Bevan (Chem. Soc. Jour, 1893, 837),  $C_6H_7O(OH)_4$  in its simplest terms.

*Introduction of Dye to Fibre.*—Osmosis probably plays an important part in the process of dyeing, and it might be possible to institute experiments, comparing the osmotic pressure of dyes, through inert membranes, with the results obtained with fibres under similar conditions. It is perhaps necessary to point out here that dyes are nothing but organic salts exhibiting specific optical effects which will not influence, or distinguish them from similar colourless organic bodies in their action towards fibres.

One can only imagine that the dyes are introduced to the interior of the fibre by osmotic action. Under these circumstances it is probable that the rate of dyeing is more due to this action than to any other, chemical or mechanical.

The following general laws will therefore govern the rate of dyeing:—

(1)\* The pressure (osmotic) is proportional to the concentration of the solution, or proportional to the volume in which a definite volume of the substance is contained.

(2.) The pressure increases for constant volume proportionately to the absolute temperature.

(3.) Quantities of substances (dissolved) which are in the ratio of the atomic molecular weights of the substances, exert equal pressure at equal temperatures.

Diffusion being caused by osmotic pressure (W. Norst, Zeits. f. Phys. Chem. 2, 613), and the rate of diffusion increasing with temperature (Graham), the practical results in dyeing seem to fall in well with the above facts.

Fick's law "that the quantity of salt, which diffuses through a given area is proportional to the difference between the concentration of the two areas, infinitely near to one another," has been since verified and found to be true for gelatin or agar-agar solutions. Animal membranes were found to alter the process, which took place, and the results were, roughly, half those obtained with the purely osmotic phenomena. The flow of the dissolved

If this dye be diazotised and combined with phenols, amines, or other suitable compounds, azo dyes of various colours are produced. As Mr. Green has fully pointed out in this Journal (Vol. VII., 179), these colours can be produced on the fibre. Under these conditions the colours are remarkably resistant to the action of soap solution, in this way resembling the so-called adjective colours, such as alizarin-red on an alum mordant; although one cannot in any way compare them to the latter class of dyes, for they are completely soluble in alkaline or soap solution. Speaking generally, they are soluble in both acid and alkalis when phenols are used as developers, and only in alkalis when these are replaced by amines; neither can these colouring matters be compared with the so-called "substantive colours," which dye on to cotton without mordant. Although some of these are very resistant to the action of soap when dyed on that fibre, yet they are comparatively speaking "loose" when dyed on silk.

Some other explanation to that generally given for the process of dyeing will have to be devised to explain their general behaviour to reagents, the colours being soluble in alkaline solution, and yet fast against the action of soap. On preparing some of these azo dyes outside the fibre, and dyeing the same direct, the colours were not resistant to the action of the same reagents. With a view to studying this question more fully, the following experiments were instituted. These were all performed on silk, and without confirmation must not be taken to apply to other fibres. It is necessary to consider these individually, for even in physical properties, such as shade, and fastness, against light and reagents generally, the results obtained on different fibres are not identical.

substance was hindered, but not stopped. An osmotic rise in pressure took place, but did not reach its true value (Zeits. f. Phys. Chem. 3, 316).

This is probably a similar state of things to that obtained in dyeing, although it is not denied that minor factors may modify the direct results.

E. J. Mills and T. Hamilton have shown (this Journal, Vol. VIII., 263) "that under certain circumstances the proportion of two mixed colours dyed on wool is the same as that in which they existed in the vat before dyeing." This result also corroborates the above idea, falling in with law (3).

Cross and Bevan (this Journal, XII., 104), although dealing with the more inert cellulose and ligno-cellulose fibres, come to the conclusion that there is a direct reaction between ferric ferricyanide and ligno-cellulose, similar results being obtained with gelatin.

*Ingrain Colours.*—With the object of, if possible, helping to clear up some of the questions in connection with this subject, the following work has been undertaken. I propose this evening to take up the so-called "ingrain colours," or rather to glance at one or two of the questions involved in the dyeing of them; for I find that the complete study of this subject cannot be entertained in the short space devoted to this paper, involving, as it would do, hundreds of experiments. I also saw that I should have to confine my experiments within comparatively narrow limits, only ascertaining that the results held good on a more liberal scale. It was therefore decided that these experiments should be confined to the study of the colouring matters obtained from *p*-toluidine, which are sent out under the name of "Primuline." Mr. A. G. Green kindly informs me that this dye contains 10 per cent. of dry sodium carbonate, 20–30 per cent. of dehydrothiotoluidine sodium sulphonate—

and the rest amidobenzenyl-amido-thio-cresol sodium sulphonate—

*Experimental Results.*—In all the following experiments the following standard method of dyeing was adopted. Six samples of silk, weighing 1 grm. each, were boiled in 400 cc. of distilled water with 1 per cent. of primuline. At the end of a quarter of an hour 2 grms. of sodium chloride were added, and the solution kept at the boil for 10 minutes; and then 1 cc. of 30 per cent. acetic acid added, and the dyeing continued for a further 35 minutes. By this means the fibre was evenly dyed.

The standard soap solution used in all cases was a 0.4 per cent. solution of olive-oil soap, containing 1 per cent. of free KHO, the standard soda solution being a 0.4 per cent. solution of dry sodium carbonate. The temperature was kept at 95°C., 500 cc. of boiling-out liquor being used for every grm. of silk.

No. 1. The action of soap solution on primuline itself was first studied, with the following results:—

No.	Time of Boiling.	Loss of Colour.
	Mins.	Per Cent.
1	5	0.10
2	10	0.20
3	15	0.30
4	30	0.30
5	60	0.60

In order that the loss of colour might be noted with as much accuracy as possible, independent samples were dyed with varying amounts of colour, and the shades obtained used for comparison with the above. This was the general

\* Only holds good for indifferent substances.

method adopted in this paper, although many of the results were obtained by colorimetric methods. The latter method was considered to be the more accurate when small quantities of the dye were removed.

No. 2.  $x.N_2.C_6H_4.OH$ .—Six samples were dyed as above, with 1 per cent. primuline, diazotised, and combined with phenol in alkaline solution, and the resultant shades were boiled out in standard soap solution, with the following results:—

No.	Time.	"Ingrain" Loss in Colour.	"Direct" Loss in Colour.
	Mins.	Per Cent.	Per Cent.
1	5	0.03	0.10
2	15	0.09	0.50
3	30	0.15	0.57
4	45	0.18	0.65
5	60	0.20	0.74

The results in this and similar cases have been entered under the column "Ingrain," and all through the paper results obtained in this way, by diazotising on the fibre, will be thus designated.

Six samples were dyed "direct," with an amount of the phenol azo dye, (prepared outside the fibre) equivalent to 1 per cent. of primuline, in standard dye liquor. After dyeing for one hour, all the colour had gone on to the fibre, and the samples were then passed through soap solution under standard conditions; the above results were obtained. The two sets of results are also plotted as curves, and the difference in colour, if any, is noted in the table devoted to that subject.

No. 3.  $x.N_2.C_6H_4.NH_2$ .—Six samples were dyed with 1 per cent. primuline, and, after diazotising, combined with aniline in acid solution, and the resulting shades boiled out in standard soap. As with all azo dyes prepared with amines from primuline, it was found necessary to dissolve the dye in slight excess of NaHO for the "direct dyeing"

set of samples, for the colouring matter is insoluble in acid solutions. Care had to be taken in dyeing, not to acidulate the dye liquor until nearly all the colouring matter was fixed on the fibre. Otherwise the treatment was identical with that adopted in the case of the phenol compound. The results are given in the tables.

No. 4.  $x.N_2.C_6H_4.N_2.C_6H_4.NH_2$ .—Another case that will require special mention, is that of the "azotriple" colouring matter, obtained by rediazotising the above amino-azo colour, and recombining with the same base. The direct dyeing was conducted in the usual way, with dye prepared by rediazotisation, and combining with aniline, and like the previous dye was insoluble in acids.

No. 5.  $x.N_2.C_6H_3(COOH.OH)$  (alkali yellow or cotton yellow R).—A yellow dye is put on the market of the above composition, prepared by combining the diazotised primuline with ortho-oxybenzoic (salicylic) acid.

No. 6. The results obtained by acting on the diazotised primuline with ammonia are also added to the list. The composition of this yellow dye is unknown, but the ingrain colour is very fast against soap. It is known in commerce under the name of "mimosa."

No. 7. Atlas Red R.  $x.N_2.C_6H_3(NH_2)_2$ , is prepared by diazotising primuline and combining with *m*-tolylene diamine. It gives a scarlet on silk. Diazotised and combined with  $\beta$ -naphthol a brown dye is produced. The results obtained with this colour will be found in the general table.

The results obtained with other developers and dyes are tabulated as follows, and the different sets of curves are also given in the different diagrams.

*Action of other Reagents.*—In order to find out whether the above general results were obtained with other reagents besides soap, the action of sodium carbonate solution on the different dyes was studied. An example is given. The aniline azo dye was used. A 0.4 per cent. solution of dry sodium carbonate was employed, the ratio of solution to silk being kept the same as in the previous experiments with soap.

*Microscopical Examination of Dyed Fibre.*—No difference, as far as evenness of colour was concerned, could be noticed between the fibre dyed "ingrain" and "direct."

It will be seen from the above table that the results vary very much with different developers. Perhaps this will be more clearly seen in the set of curves on the diagrams. Before alluding to this matter, however, I wish to point out that the colours obtained by ingrain dyeing are not identical with those from the direct method, as the following table will show:—

Dye.	Developer.	Colour Obtained.	Method of Dyeing.
Primuline	$C_6H_5.OH$ .....	Yellow.	Ingrain.

Most striking, too, is the result obtained with the aniline azo triple dye, its resistance ratio being as 1:1.7 when compared with the azo dye itself.

The results with Atlas Red R and  $\beta$ -naphthol do not exhibit that fastness which should correspond with the azo triple dye from primuline and aniline; but it must be remembered that the dye is of a phenolic nature, and in this way perhaps falls in with the previous remarks. Thus, without any evidence to the contrary, we may take it for granted that the relative fastness depends more on the phenolic or basic nature of the dye than on the internal structure of the dye molecule. These remarks of course only apply to primuline dyes, but will probably be found to be true for all similar bodies.

Some azo dyes cannot be developed on silk. Take, for instance, the dye produced from  $\beta$ -naphthol sulphonie acid ("R salt") and diazotised primuline.

According to the general law of osmosis as previously mentioned, this difference can hardly be due to difference

*Observations on Curc.* It is not proposed in this paper to discuss the question from a mathematical point of view, but only in a general way.

It will at once be seen that the results obtained are strikingly at variance with any simple theory of solid solution, for in that case the curves from the direct dyeing method should coincide with the ingrain dyed curves. This is not the case, and it will be further noticed that the direct dyeing results show that the dyes are more easily removed than the original primuline itself, while the ingrain dyes are very resistant to the action of soaps and alkali, and therefore must be taken to be in combination, in some way or other, with the fibre itself. This will be better seen by the following table, where the results in each case after one hour's boiling are tabulated and their ratio shown.

It will be noticed that the alcoholic or phenolic azo dyes do not resist the action of the soap to anything like the extent that the amine compounds do. Take, for instance, the figures for resorcinol and *m*-phenylene-diamine respectively—4.4 and 15.4. These general results will be noticed all down the column except in the case of  $\beta$ -naphthylamine, which does not give a very resistant ingrain dye when compared with the other amine derivatives. It might be argued from these general results that fibron shows a more acid than basic reaction, but this point is simply noticed in passing.

in diffusion of the developers, as has been suggested, for quantities of substances (dissolved) which are in the ratio of the atomic molecular weights of the substances, exert equal pressure at equal temperatures." I have come to the conclusion that the phenomenon is due rather to a compound being formed by the diazo compound with the silk itself, which the "R salt" is unable to decompose.

The resistance of primuline itself (as seen by the curve) against soap is, as a matter of fact, greater than the resistances of many of the azo dyes themselves, and this partly corroborates this suggestion.

When this silk is dyed in the first place with primuline, we may take it for granted that a combination takes place between the primuline base and the fibron; then on diazotising, the primuline is diazotised, and perhaps partly combines with the silk again, and then the developer, if powerful enough, will form the dye. It is hardly possible that this truly represents the reaction, but it may help to give an idea as to what might take place when the colour is

produced in the fibre,--one has a soluble dye on the one hand and a fibre on the other. There must either be a chemical combination or simply a mechanical action, such as the withdrawing of alkaloids from aqueous solution by ether.

If we accept the latter statement as representing the true state of affairs, we are face to face with the fact, fully established in this paper, that when the dye is presented to the fibre under different circumstances, totally different results are obtained. I can see nothing for it but to fall back on the chemical theory and believe that this with modifications, supplemented by a theory of osmosis, will most truly represent the action that goes on when azo dyes, such as primuline, are dyed "ingrain."

**False Zero.**—It was necessary to allow for the amount of dye that would still remain on the fibre when an equilibrium was established between the dye solution and the silk. In order to estimate this, 1-grm. samples were dyed in 500 cc. of 0.4 per cent. soap solution containing 1 per cent. of the dye in question. The dyeing was continued for an hour; the silk was then removed from the dye-bath, thoroughly washed, and passed through acetic acid. After drying the percentage of dye on the fibre was estimated by comparison. Of course the ratio of the quantity of solution to dye would greatly influence the result, and with a much larger quantity of the former would more nearly approach the true zero (100 per cent.).

The results obtained by dyeing as above were as follows:—

Dye.	Per Cent. of Dye taken up by Fibre.	—
Primuline and $C_6H_5.OH$ .....	0.18	Diag. 1.
" " $C_6H_5NH_2$ .....	0.19	"
" " $C_6H_5(NH_2)_2$ .....	0.11	Diaz. 2.
" " $\beta C_{10}H_7.OH$ .....	0.12	Diaz. 3.
" " $C_6H_5.COOH.OH$	0.11	Diaz. 5.

In conclusion, I would point out, that the above results tend to connect up a link in the chain of a mechanico-chemical theory of dyeing—that is, a theory that depends primarily on a diffusion process obeying a modified form of the general laws of osmosis, supplemented in some cases, if not all, by a chemical, or series of chemical, reactions between the fibre and the dye. Whether this can be brought under the term "solid solution," even in its widest terms, is extremely doubtful, for one must then acknowledge that the "solubility" (?) of the dye dyed "direct" is greatly altered when dyed "ingrain."

#### DISCUSSION.

Mr. A. G. GREEN said they were much indebted to Mr. Dreaper for the careful quantitative study of the dyeing affinities of the ingrain colours, because it was only by the quantitative study of matters of this kind that any satisfactory theory of dyeing could be arrived at. The fact that the fastness of the ingrain colours formed upon fibres was immensely greater than the fastness of those same colours when made separately and then applied to the fibre, he had noticed many years ago. He had been rather inclined to favour a mechanical explanation. When an azo colour was built up in a fibre, one might suppose that the pores of the fibre were only sufficiently large to accommodate the primuline molecules or aggregate of molecules, and were tolerably completely filled up; then if you converted the primuline into an azo colour the molecules were greatly increased in size, and consequently had a greater difficulty in getting out when the cotton was boiled in a soap solution. It was quite possible, however, that the question was a chemical one. Mr. Dreaper's experiments only applied to silk, but exactly the same thing was found in the case of cotton. Many of these colours when made separately had a certain affinity for cotton fibre; for instance, that derived

from metaphenylene diamine; whilst in other cases, *e.g.*, the colour from betanaphthol, the affinity was very small. If the same colour were applied to cotton "direct" and "ingrain," it was always found that the ingrain colour resisted the action of boiling soap to a far greater extent than the colour applied direct. There was a good deal of evidence to show that primuline on the fibre was really in a state of chemical combination; for instance, take the sensitiveness of diazotised primuline on the fibre to light. If diazo-primuline were made separately and then applied to the fibre, it was very stable to light and was hardly affected at all. If you took two pieces of cotton, one dyed with primuline, and then diazotised the other, to which the same quantity of finely-divided diazotised primuline had been mechanically applied, the first would be completely decomposed on exposure to sunshine in a few minutes, whereas the other would remain completely unchanged for some hours, showing there was a considerable difference in chemical properties in the diazotised primuline when formed on the fibre, and when formed in a separate condition. The behaviour of dehydrothiolumidine sulphonic acid, the compound from which primuline was derived, was very curious. It differed from primuline in having no affinity for cotton, and was colourless, whereas primuline was yellow. But it would dye silk in the same way as primuline, that is to say, the silk would take it up, although without being coloured; this colourless silk could be developed just as if dyed with primuline, giving very similar ingrain colours. This was the only case which he had yet met with of a "colourless dye," if he might use the expression; that is, of a colourless substance possessing dyeing affinity. He had tried the sulphonic acids of a great number of phenols and amines, but had never found any possessing an affinity for animal or vegetable fibres.

Mr. F. EVERSHED asked how Mr. Dreaper estimated the quantity of colour removed from the fibres, and how long it was necessary to diazotise these silks. Also in some cases where the silk was dyed with primuline and afterwards developed, might not some of the colour attributed to the primuline be due to what one might call the silk colour, *e.g.*, that formed from silk itself?

The CHAIRMAN said that of the dyeing of fabrics he knew little or nothing, but he should like to ask Mr. Dreaper if there was anything to show whether ingrain colours had their additional fastness by reason of a combination between the material of the fibre and the colour, or whether it was simply that the colouring matter was formed inside the fibre, and therefore enclosed. Many substances apparently could only with great difficulty be washed out from a fibrous matter such as cotton fibre, simply because they require a very long time. The soluble substances thus enclosed only passed out by a process of dialysis, and that required time, whereas if they were external they were readily washed out.

Mr. DREAPER, in reply to Mr. Evershed, said that the pieces of silk after about a quarter of an hour showed a distinct yellow tinge. His idea was that primuline might fill up the pores of the fibre, and the azo dye formed from it might occupy more space and be held in the pores in the same way that alizarin dyes were supposed to be fixed on the fibre. He did not see how this could be the case, because the dye itself was soluble in alkali, and would at once be dissolved, and then it would only be a matter of exosmosis, or of the dye diffusing out of the fibre.

Mr. GREEN said the larger the molecules were, the faster the colour was. Mr. Dreaper's numbers for the azo triple base seemed to bear out his idea.

Mr. DREAPER suggested that might be because it was more basic, the aniline curve being faster than the phenol one. If the dye were not in combination with the fibre it would immediately go into solution when boiled with alkaline soap, and then more or less rapidly leave the fibre. He had noted the rate at which these developers diffused into the

fibre; they did not take longer than five minutes, judging from the rate at which the colours developed. It was the soap or sodium carbonate which diffused into the fibre, that would govern the rate of loss in colour, supposing that the dye was mechanically held in the fibre. He questioned whether, in the case of silk, it could be said to contain pores; it was more like a solid rod; it was not like cotton at all. There were no internal cavities. It was not likely that the silk colour formed on the fibre would materially interfere with the primuline result, for the length of time that the silk was in the nitrous acid would not be sufficient to diazotise the fibre. The Chairman had also put a question whether the ingrain colour was in combination or was simply inside the fibre. As far as he had gone, a microscopical examination showed no difference in the fibre; and from Knecht's, Vignon's, and other workers' results, one would imagine the colour must be in combination with the fibre. Undoubtedly if one dyed silk with a basic salt, and had the base going on to the fibre and the acid left in solution, it must be, as Knecht said, a chemical reaction, because the dye salt itself was split up. Primuline was much the same kind of body, and one might get the primuline base combining with the fibrous and sulphonic acid remaining in solution.

Mr. GREEN said that could not be the case; primuline was a sulphonic acid of the primuline base, not a sulphate. Moreover, as regards the possible greater basicity of the azo triple base, he thought that would not be so, since the proportion of the amido-group to the rest of the group was actually smaller. With regard to solution on boiling with alkaline soap, he would remind the author of the paper that the dyestuff was enclosed in a fibre, through which it had to diffuse. In the case of the developer, beta-naphthol, the molecular weight was 143 only, whereas the primuline molecule was 500 or 600. The molecular weight of primuline azo-beta-naphthol would be somewhere about 700. He thought silk might have internal cavities, though small ones.

Mr. DREAPER said the primuline curve on the diagram showed that that body had greater affinity for the fibre than many of the azo dyes derived from it. If dyed "direct" it was simply a matter of diffusion. According to the molecular weight, it would diffuse more readily than the azo triple bases. If the primuline were not in combination in some way with the fibre, by the general law of osmosis the primuline should diffuse out of the fibre into the liquor, and be boiled off to a greater extent than the azo triple dye dyed "direct." This was not the case; in fact, the primuline was much more resistant than the azo triple dye.

Mr. GREEN thought Mr. Dreaper's explanation could not hold true, because it would not apply to cotton, and he had observed exactly the same results working qualitatively in that case as had been described. The fastness of primuline on cotton was intermediate between the fastness of the ingrain colour made from it and the same colour made separately and then applied. He was not prepared to explain it. It appeared to him very difficult to find a chemical theory of dyeing which would include the dyeing of cotton.

Mr. DREAPER said cotton was not an amido compound, and must be taken separately when considering the general theory of dyeing.

## THE MANUFACTURE OF STRAW CELLULOSE.

BY JAMES BEVERIDGE.

THE manufacture of cellulose or paper pulp from the various kinds of straw is so well known to experienced paper-makers that it is probably difficult to mention anything specially new in dealing with such a subject. This statement may also be made in regard to other fibrous plants besides straw, and it may be deemed unnecessary by some that one should occupy the time of our Society on such a trite subject. The manufacture as a whole is, however, unquestionably a difficult one, and there are certain problems associated with it which are of great importance to pulp and paper-makers, and certainly of more than passing interest to the technical chemist.

Straw has been used for paper-making from very early times. It is said that the Chinese manufactured paper from rice-straw before the Christian era. This art originating with them gradually extended to Europe through Spain, Germany, France, Holland, and finally to England. The rapid development of the industrial resources of Europe at the beginning of this century, and our ever increasing social requirements demanding the extension of our paper industry, told heavily on the supply of rags, and gave a great impetus to the manufacture of paper pulp from fibrous plants. The scarcity of rags to meet these requirements not unnaturally caused paper makers to turn their attention to straw, because of its universal distribution and abundant supply. The invention, too, of a method of manufacturing a comparatively cheap and inexhaustible supply of alkaline soda products from common salt by Leblanc practically placed the chemical treatment of straw—as indeed all other fibrous plants—on a sound manufacturing basis. Since that period and the rise of the alkali industry in England, the inventions of Weldon and Deacon relating to the manufacture of cheap chlorine have added

much to the development of the straw pulp industry. Indeed, it may be said with perfect truth that the success of this manufacture to-day fluctuates with the market value of soda and bleaching powder.

There are two kinds of pulp made from straw, viz. straw pulp proper, and what may be more correctly termed straw cellulose. The former is made by steeping the straw, or boiling it under pressure, with milk of lime until it is thoroughly softened, after which it is washed and ground with suitable machinery and manufactured into a cheap quality of wrapping paper. This method is employed extensively in France and other countries of the continent where there is a demand for such papers, but, so far as I am aware, is not used in England to any great extent, excepting probably in the manufacture of strawboards.

Although the subject of this paper has nothing to do with this kind of straw pulp, yet it may be mentioned incidentally that the chemical action of the milk of lime on the incrusting materials surrounding the straw fibre is not a vigorous one. These incrusting materials are not completely, nor indeed to a great extent, separated from the cellulose. The mineral matter remains in the product practically untouched, and if any less quantity than that corresponding to the percentage in the original straw operated upon exists in the prepared pulp, it is due rather to the washing after digesting than to any solvent action of the milk of lime. The milk of lime, under certain conditions, has a bleaching action on the straw. It neutralises the organic acids usually formed when fibrous plants are heated for any length of time in presence of water. The yield of pulp obtained by such a treatment amounts to from 75 to 85 per cent. The papers produced from this pulp are of a very poor quality, and wholly used for packing purposes. They are hard, brittle, and possess a low tensile strength.

The preparation of pure cellulose from straw is a very different manufacture, and involves a cycle of operations, each one of which requires the most careful supervision. The product is used for the production of papers of first-class quality, fine and medium writings, for example, and must be well prepared, and as free from dirt as it is possible to get it. It is therefore necessary that cleanliness be observed in every department, and that the straw itself and the water used for washing, &c. be subjected to a preliminary purification as necessity may require before they enter the mill. It will only be necessary for me to touch lightly upon a series of operations through which the straw passes, and in order to make the whole subject plain, I will subdivide it into the following divisions:—

I.—Straws. Their composition, nature, &c.

II.—Manufacturing operations—

(a.) Cleaning, cutting, and dusting.

(b.) Digesting the straw in caustic soda lye.

(c.) Washing, breaking, purifying, and bleaching.

III.—General data *re* (a) yield, (b) bleach, (c) loss of soda, &c.

IV.—Fuel and mechanical power required to produce a ton of straw cellulose.

#### 1.—Straws: their Nature and Composition.

The straws usually employed for the preparation of cellulose are those obtained from the cereals, oat, wheat, rye and barley. In some parts of the continent maize straw has also been used, but I understand with only moderate success, as it yields a somewhat coarse fibre. Next to wood, oat, wheat, rye, and barley straws are the most universally distributed fibrous plants, known as sources of paper pulp. In point of cheapness they also rank next to wood, which is recognised as the cheapest source of cellulose at present known in this country. The physical character and composition, especially with regard to their ash contents, vary enormously. This is not only true of the different kinds of straw, but also of the same variety, and seems to depend upon the district or country in which they are grown. Probably the soil has influences on the composition of the ash as well.

The fibres contained in these straws are loosely bound together by resinous and intercellular matter, which is easily dissolved by caustic soda, and subsequently separated by washing. Thus isolated they are soft, flocculent, and admirably adapted for use in the manufacture of high-class writing papers. They differ slightly from one another in their paper-making qualities; the fibres from barley straw, for example, differing from those of oat, wheat, and rye in length, breadth, and general physical character. This difference is very noticeable when the pulp from each of these straws is separately brought forward in the mill. It is not very difficult to classify the straws according to the nature of the fibre or cellulose they yield, although such a classification as I am about to attempt is true only locally. My experience being confined to Dutch straws, the following bears directly on them:—

*Barley straw* yields a short, very soft fibre of low felting power. The knots and husks are soft, and in consequence this kind of straw is easily digested.

*Oat straw* is usually somewhat harder; the knots and husks are more difficult to digest. The fibres it yields are comparatively long, soft, and of medium felting power.

*Wheat and rye straw* are, according to my experience, closely allied. They both yield long fibres of good felting power, and are the most valuable as sources of cellulose. Rye straw in particular yields cellulose of excellent quality, and as it usually contains a comparatively small quantity of mineral matter, it is soft and easily digested.

The classification of these particular straws grown in other countries would doubtless be different, because the amount of ash they contain controls to a large extent the facility with which they are converted into cellulose.

The composition of these straws, according to Müller, an oft quoted authority, also varies enormously. His analyses, which I reproduce, plainly shows this:—

COMPOSITION OF STRAWS (MÜLLER).

	Winter Rye.	Winter Wheat.	Summer Barley.	Winter Barley.	Oats.

The estimation of the cellulose in fibrous plants by the method recommended by Müller is a long, tedious process, and is difficult to perform with accuracy in the laboratory. In my opinion it is uncertain, and requires experience and the exercise of great care in order to obtain concordant results. Few paper or pulp makers will believe that the percentage of cellulose obtained by him in some of the above examples really represents the truth. Some of them, according to my experience and researches, are unquestionably high, and cannot be taken as representative of the class of straw to which they relate. Although it is impossible to assign a definite percentage of cellulose to any one class of straw, yet practical manufacturing yields are fairly constant and it is very probable that Müller has included other organic matters closely allied to cellulose in the percentages given under this heading in his table.

It is manifest that a process is required for quickly estimating the cellulose available for papermaking in fibrous plants, especially one that will be fairly accurate and yield results more surely indicating the yield it is possible to get

in manufacturing practice. It is well known that weak aqueous solutions of bisulphites of soda, lime or magnesia, at moderately high temperatures, do not dissolve cellulose, whereas solutions of caustic soda or potash do, and they can be said to dissolve cellulose at all. The method of estimating the cellulose in this way seems to me to yield much more satisfactory results than Müller's method, and I have used it for many years for ascertaining the amount of cellulose in a great variety of fibrous plants and for the use of paper stocks. By digesting a known weight of the plant, straw, or an aqueous solution of bisulphite of soda, lime or magnesia, and after washing, bleaching, and drying, taking an allowance for the mineral matter in the pulp, the percentage of cellulose may be readily calculated. This method yields results invariably much lower than Müller's figures, and very closely resembling manufacturing yields, and therefore I believe more truly represents the cellulose available for papermaking purposes. Some of the results obtained by this method are the following, viz.:—

#### COMPOSITION OF STRAWS.

\* Air dry cellulose containing 10 per cent. of moisture. Air dry straw containing moisture as shown above.

It will be noticed in both of these tables of analyses that the percentage of oven dry cellulose in the oven dry straw has been calculated in each case for comparison, and that the descending order in which the straws indicated yield in my own table is as follows, viz.:—rye, oat, wheat (average), and finally barley. On the other hand, the order, according to Müller's table, is different: rye, wheat, barley, and oat. If the results from both tables be compared, the difference between the percentages given for each class of straw is so great that, as I have previously stated, the experienced pulp or paper-maker would decline to accept Müller's results as representing the truth. Of course, I am well aware that this depends entirely on what one calls "cellulose." If the organic intercellular matter, insoluble in ether, benzol, and ammoniacal water, which binds the individual fibres together in the plant can be considered as cellulose, then Müller's figures are no doubt correct. On the other hand, this intercellular organic matter appears to offer little resistance to the solvent action of weak caustic alkalis and bisulphites, and certainly from a paper-maker's point of view, cannot be considered as available for his use.

#### 11.—Manufacturing Operations.

(1.) *Cleaning.*—The straw as it is brought from the stacks or store house is first of all passed through a machine to thoroughly open it; or this may be done by hand. It is then delivered or placed upon tables made of wire gauze,  $\frac{1}{2}$ -in. meshes, alongside of which girls stand whose duty it is to remove all weeds and other plants likely to produce what is known as shieve, in the finished pulp. From these tables it is elevated either automatically or by hand to the cutter, which usually consists of an ordinary chaff-cutter used by farmers. The straw is fed continuously by an endless travelling belt through an orifice across the face of which, at right angles to the feed, a wheel revolves, having one or more knives attached to its spokes. The length of cut varies from  $\frac{1}{2}$  in. to  $1\frac{1}{4}$  in. From this the chaff falls on to an inclined jogging sieve of  $\frac{1}{2}$ -in. wire gauze and in travelling to the lower end the bulk of the sand, husks, and fruit grains are separated. Although the chaff at this stage is tolerably well cleaned, some manufacturers prefer to give it a final dusting, and to do this they employ a revolving sieve, through the centre of which a shaft revolves at a high

velocity. This shaft has pegs studded along its length at equal intervals, and so placed as to form a kind of archimedean screw. The sieve is cone shaped or slightly inclined, and as the chaff travels forward, all loose dust is separated, being carried through the meshes by the current of air induced by the revolving shaft. It is then stored in heaps ready for the pulp boilers.

The object in subjecting the straw to such a trenchant system of cleaning as above indicated is to remove all foreign weeds, husks, fruit grains, and sand. This is absolutely necessary for the production of high-class pulp, for it has been found by experience that these impurities produce more or less unbleachable particles, and much of the success attained in avoiding these imperfections depends on the completeness and care with which the straw is primarily cleaned before it enters the pulp boilers. The loss incurred by cleaning will depend upon the quality of the straw, but it should not exceed 5 per cent. of the total weight operated on.

(B.) *Digesting the Straw in Caustic Soda Lye.*—The boilers usually employed for doing this are of the rotary type—either cylindrical or spherical. Very seldom are upright stationary boilers used. The reason of this seems to lie in the necessity of keeping the mass within the boiler in a continual state of motion, so that each particle of straw will be equally acted upon by the caustic lye. This cannot very well be attained in stationary boilers, even with the usual vomiting arrangement, because the chaff, when softened by the lye, sinks down into such a dense solid mass as to interfere with the free circulation of the lye through it.

Of the two rotary boilers mentioned, the spherical type offers certain advantages over the other. It occupies relatively less floor space, is more easily filled and emptied, and presents less radiating surface per unit of capacity. These boilers are usually provided with two manholes, a blow-off cock, &c., and are heated by steam injected through the trunnion. Motion is given to them by means of worm gearing fixed to the standards supporting the boiler.

The strength and volume of the caustic lye employed necessarily vary in different mills, according to the kind of straw used and upon other conditions peculiar to the nature of the apparatus in use, e.g., the steam arrangements of the factory. Both are slightly modified when barley straw is used alone, but as in actual practice the best results are obtained by mixing the different kinds of straw and keeping the mixture as nearly as possible constant, any rule laid down with respect to the proportion of caustic lye required is adhered to from day to day. The actual quantity of caustic soda, reckoned as 60 per cent. alkali, also varies slightly with different kinds of straw, as well as on the temperature and speed with which the digesting operation is carried out. Where the temperature is high and the time given for the boiling is long, the caustic is reduced to a minimum.

The following figures, representing the "charge," &c., of a straw pulp boiler, is from actual practice:—

Weight of straw (mixture of oat and wheat)	4,480 lbs. (40 cwt.)
Gallons of caustic lye	1,610
Hours under steam pressure	4
Steam pressure above atmosphere	60 per sq. in.
Maximum temperature	307° Fahr.

#### CAUSTIC LYE.

Twaddell	10½
Total weight in pounds	16,945
Percentage by volume of Na <sub>2</sub> O	0.3249
" " " 60 per cent. alkali	0.5416
Total 60 per cent. caustic soda in pound	872
Pounds of 60 per cent. caustic alkali on 1 cwt. of straw = 21.8.	

The operation of digestion is very simple. The pulp boiler is filled as full as possible with the cut and cleaned chaff and the required volume of caustic lye run in. The manlid door is then put on and a small quantity of steam admitted, while the boiler is made to revolve for 15 minutes or so in order to soften the straw and cause it to subside to make room for more. When this is done the lid is again removed and the vacant space within the boiler filled up

with more straw. In this way the charge of straw per boiler is increased from 15 to 20 per cent. When the boiler is thus filled and the manlid fastened on, high pressure steam is injected into the charge through the trunnion, and the pressure gradually raised to the desired degree. The pressure varies in different mills, but as a rule it registers from 60 to 90 lbs. per square inch. This pressure is reached after about two hours steaming, and is further maintained for 4 or 4½ hours. In the meantime the boiler is kept continually revolving.

(C.) *Washing, Breaking, Purifying, and Bleaching the Straw.*—After the digesting operation has been completed, the whole contents of the boiler are emptied into a tank placed beneath it, where the crude cellulose is washed with hot water. It is necessary to accomplish this work with the least possible quantity of water in order to avoid undue dilution of the waste lye. The most efficient method is that of the application of the principle of displacement as carried out in the lixiviating of ball soda in the Lèblanc soda process. It is possible in manufacturing practice to remove 95 per cent. of the soda associated with the boiled straw cellulose by this system of washing with a dilution of about one-third, that is to say, the pulp can be washed in the tanks with a quantity of water, represented by one-third of the volume of black lye associated with the pulp. The weakest washings from these vats are run to waste, as it does not pay to evaporate them, even although the most refined system of evaporation be used for their concentration.

After the bulk of the black soda lye has been removed in the way described, the crude cellulose is allowed to drain, and then conveyed to an apparatus called a "breaking engine," in which it is broken up into pulp.

In this engine it is again washed to remove the last traces of soda; and a proportion of the intercellular matter surrounding the fibres as well as any dirt will pass away with the wash water. That part of the intercellular matter carried away is in a fine state of division, and if it be left in the pulp it is supposed to consume a large quantity of bleaching powder in the subsequent bleaching. As a matter of fact, however, if the straw be properly boiled in the first instance, the intercellular matter has little influence on the amount of bleach required to bleach unit weight of crude product. It is possible to wash straw pulp in the breaking engine to such an extent as to seriously affect the yield of pulp, and therefore the bulk of the washing can be most advantageously done in the tanks.

The pulp, although now broken up, so that the fibres are separated from one another, is not yet in a fit state of purity to be bleached. It invariably contains a few unboiled pieces of straw, or possibly some unboiled knots or hard weeds, and it is absolutely necessary to separate these to get a clean product. In order, therefore, to cleanse it, the contents of the breaking engine are emptied into a large tank, and pumped into special purifying apparatus. This apparatus consists of a long shoot, called a sand-trap, as a rule about 200 feet or more in length, about 18 inches wide, and 9 inches deep, containing at intervals of 18 inches or so, cross-boards about 4 inches high, and inclined towards the flow of the pulp. At the end of this sand-trap, a series of cast-iron boxes, called strainers, are placed. These strainers contain brass plates, having very fine slits cut in them, and it is through these slits that the individual fibres pass, whilst the rough, hard, unboiled pieces are retained. After the pulp passes through these slits, it is practically pure and clean. The width of slit of course regulates to a certain extent the degree of purification required.

The pulp before entering this apparatus is largely diluted with water to enable the particles of sand, dirt, and heavy weeds to subside as the mixture flows over the submerged cross-boards. Any impurities which pass the sand-trap are retained by the strainer plates.

It is now necessary to remove the large excess of water from the cellulose before bleaching, and this is done in a variety of ways, one of the best being by means of a machine called a "tambour." This is simply a skeleton cone made of hard wood and covered inside with fine brass wire gauze. The whole is mounted on a horizontal shaft running through its centre, and as the pulp flows into the narrow end, as it

revolves, the water passes through the wire gauze, whilst the pulp is discharged from the wide end, in a concentrated state, into a reservoir, from whence it is pumped into the "potcher."

The "potcher" is constructed on the same principle as the "breaking engines," but as the name implies, is used simply as a mixing machine. When full, a certain volume of a clear solution of bleaching powder is added, and the stirring continued for an hour or two, when the whole charge is run off into large concrete tanks, fitted with false bottoms of perforated tiles. In these tanks the mixture of pulp and bleach liquor is allowed to remain for 12 or 16 hours, by which time the hypochlorite will be exhausted, and the pulp of a white colour.

It is only necessary to allow the spent bleach liquor to drain away, by drawing a plug from its seating in the bottom of the tank, and then removing the cellulose to another tank, where it is mixed with clean water, and finally pumped on to the paper machine, by which it is converted into a thick sheet of paper, in which state it is sold.

The foregoing in effect embraces the routine of this manufacture. The apparatus, both in arrangement and detail, is modified in different mills. The operations are simple, and require no great skill to carry them on successfully, but the chemical problems involved in the economical production of straw cellulose are more difficult to deal with, and I now propose to touch upon the most important of them.

### III.—Yield, &c.

It has always been the aim of manufacturers to obtain the highest yield of cellulose from unit weight of straw, and to this end various modifications of the soda process have been suggested and worked on a manufacturing scale. A process with this intent was brought out some years ago by Leunig and worked by an English company, but the results were very indifferent. Caustic soda was used to remove the incrusting organic and mineral matters surrounding the fibres substantially in the manner above described, but instead of bleaching with hypochlorites chlorine gas was employed. This, as is generally known, is a costly and anything but an easy process to carry on economically and free from nuisance, if not actual danger, and it is not surprising that the Leunig process proved unsatisfactory from a commercial point of view.

From what I have previously stated it might be inferred that a sulphite process for the treatment of straw would prove of value, inasmuch as by it the maximum yield of pulp would be obtained for the reasons already given—namely, that cellulose is less soluble in solutions of bisulphites of lime, soda, or magnesia than those of caustic soda. Notwithstanding that this is substantially true there are yet serious defects attached to the quality of the product which render it practically worthless for use in the manufacture of papers of a high quality. This arises from the fact that the silica in the straw remains untouched by the bisulphite solutions, and appears in the cellulose in a very objectionable form. When such cellulose is converted into paper, the silica appears upon the surface of the sheet as small shining scales. It is also obvious that there is only one available method of cheaply removing this silica, which consists in

dissolving it out with a weak solution of caustic soda. My experiments in this direction have proved that this can be done, and that the cellulose produced by this dual treatment is of first-class quality. The yield, however, remained substantially the same as that obtained by digesting the straw in caustic soda alone. In this, as in the Leunig process, all organic substances readily soluble in weak caustic solutions are removed.

Some very interesting figures on the question of yield which I here reproduce were given in the *Papier Zeitung* some few years ago by Roth. I understand them to be the results obtained in actual manufacture, and as such are very instructive to the pulp and paper maker. They clearly show that the yield from unit weight of straw varies inversely with the quantity of caustic soda used for digesting, and that the amount of bleaching powder required to bleach the pulp varies directly with the yield. Assuming the temperature (or pressure), the time used for digestion, and the quality of the straw with respect to its percentage of cellulose to be kept practically constant, I have found by a long series of experimental trials that the above conclusions are strictly correct.

These manufacturing yields as given by Roth seem to indicate that it is possible to obtain 50 per cent. of bleached cellulose from straw, but whether the product corresponded in quality to what is found in the market as straw pulp seems to be very doubtful. The fact that 7 cwt. of bleaching powder were required to bleach one ton of it plainly indicates that it was of low quality. It is of course possible to treat straw with weak caustic solutions, to obtain a high yield, but this product cannot be looked upon as "straw pulp" of ordinary quality.

In practice, the actual yield seldom exceeds 40 per cent. In one pulp mill with which I have been connected, working a mixture of oat and wheat straw, with occasionally a small parcel of rye and barley, all grown in Holland, the yield of bleached cellulose containing 10 per cent. of moisture fluctuated over a long period between 40 per cent. and 41 per cent.

The bleaching powder required to bleach this air-dry pulp varied from 18 to 20 per cent. These results closely correspond to those given by Roth in the Austrian factory.

Lately the so-called "sulphate process" has been applied in a German factory, and as the digesting fluid consists largely of sulphide of sodium, which, as might be inferred from its properties, has a less solvent action on the cellulose than caustic, it is very probable that the yield obtained in this process exceeds that of the caustic process pure and simple. I am, however, unable to state definitely whether this is so or not, or what the yield actually is.

Passing now from the question of yield, I come to another of great importance, namely, the influence of the quantity of silica in straws on the loss of soda, and a consideration of the methods for mitigating this loss. It is almost unnecessary for me to remind you that the composition and quantity of the ash found in straws varies very greatly. The most complete analyses of the ashes of straws, which I have been able to find, are those published by Wolff (Ashen Analysen). The following table embraces his average results:—

COMPOSITION OF THE ASHES OF STRAWS. WOLFF'S "ASHEN ANALYSEN."

	Total Mineral Matter in Straw.	Percentage Composition of the Ash.								
		K <sub>2</sub> O	Na <sub>2</sub> O	CaO	MgO	Fe <sub>2</sub> O <sub>3</sub>	P <sub>2</sub> O <sub>5</sub>	SiO <sub>2</sub>	Cl	
Barley straw, average of 4 analyses.....	8.10	25.40	1.92	7.53	2.62	2.18	3.94	3.91	51.43	3.75
Oat " " 8 " .....	7.77	38.37	3.99	4.23	2.53	1.70	2.66	3.06	35.08	7.09
Rye " " 3 " .....	4.32	12.16	0.74	11.10	4.45	3.19	8.97	5.57	36.86	3.68
Wheat straw, one analysis .....	3.25		1.00	6.82	1.00	1.02	3.20	5.78	65.34	0.20

While the straw is being boiled substantially, the whole of the silica passes into solution as silicate of soda. The alkali thus combined is practically lost to the pulp maker, because it is rendered inactive for the process of digestion. The quantity of alkali thus rendered useless will vary, of course, with the amount of silica contained in that quantity of straw which will produce one ton of air-dry bleached cellulose on the quantity of potash rendered soluble, and also on the chemical constitution of the silicate. There being an excess of caustic soda always present, I have assumed the silicate to be a normal one, having the formula  $\text{Na}_2\text{SiO}_3$ . Assuming this to be correct, I have calculated, as shown in Table U., first, the quantity of straw required to produce one ton of air-dry cellulose; second, the amount of silica contained in this quantity of straw; and then, finally, the quantity of soda, reckoned as 60 per cent. alkali ( $\text{Na}_2\text{O}$ ), which would combine with this silica. Going a step further, by way of example, and assuming 21 lb. of 60 per cent. caustic to be the amount required to digest 1 cwt. of the Dutch wheat straw (Hypolden) above given, the total alkali (60 per cent.) used to produce one ton of cellulose is 10.29 cwt., and of this 4.39 cwt., or 42 per cent. would be neutralised by this silica.\*

It is this loss which increases the cost of soda so enormously in straw cellulose works. Unless the silicate of soda in the waste lyes or the recovered ash can be decomposed in some practical or economical way, or the recovered ash sold as such, the present highly efficient systems of soda recovery by multiple evaporation, by which 80 per cent. of the soda can be easily recovered, are of little value to the straw pulp maker. Indeed, in most cases where the silica approaches in quantity anything like that shown in the table, the recovered ash is of little value for further use in digesting. For reasons formerly stated, it is manifest that the most economical course to follow is to select those straws only for the manufacture, which by chemical test are shown to contain the least quantity of silica.

There are several methods, alike in principle, of reconverting this silicate of soda into available caustic alkali. The most simple way consists in adding bicarbonate of soda to the solution of the recovered ash, whereby the silicate is decomposed, normal carbonate of soda being formed with the separation of free silica. The same decomposition can be brought about by pumping gaseous carbonic acid through the liquor, but as this gas is not always available, and the cost of pumping is a serious item, and that the silica thus separated is in a very gelatinous state, this system is not practicable. Messrs. Sutherland and Kynaston, who took out a patent some years ago for the use of bicarbonate, claim to obtain the silica has a heavy or granular precipitate, in which state it can be separated from the carbonate of soda liquor with comparative ease. The separation of the silica is one of the great difficulties of this process. The use of bicarbonate serves the additional purpose of replacing the alkali which is invariably mechanically lost, but if the quantity of silica and the percentage amount of soda recovered are both great it can be shown by a simple calculation that the amount of bicarbonate required to effect the decomposition, abnormally increases the volume of the alkali liquors in circulation; that is to say, more bicarbonate is used than corresponds to the soda mechanically lost.

The next most important constituent of the ashes of straws that calls for particular attention is potash. While silica is considered as an impurity and of no value, the potash, on the other hand, might be utilised and turned to account. This problem is, however, as difficult to solve as that of getting rid of the silica in the waste soda lyes. If we refer to the table of composition of the ashes of straws, it will be found that the potash is very considerable in quantity, that, in fact, it ranks next to silica in this particular. It appears highest in the oat straw, rye coming next, then barley, and finally wheat. The oat straw contains more potash than silica, indeed, 2.98 per cent. of its weight. Assuming, as before, that 49 cwt.

of this straw will yield a ton of bleached cellulose, the amount of potash which passes into solution for this quantity is 1.46 cwt., which represents nearly 14 cwt. of potash alum. The above barley straw would yield a very similar amount, whilst the rye and the wheat would yield proportionally smaller quantities.

Some years ago I made several experiments with a view to recover the potash if possible in a useful state. The separation of it from the soda is very difficult, and so far as I am aware can only be accomplished in an imperfect way by crystallisation. The solubility of carbonate of potash being much greater than that of the corresponding soda salt. Of course it is practically impossible to get the potash by itself in a comparatively pure state in this way, and commercially it is too much contaminated with soda to be of much value, excepting probably in the artificial manure trade. I have, however, attempted to obtain it in the form of an alum by neutralising the alkalies in the mother liquors, after crystallisation, with sulphuric acid, and then adding sulphate of alumina and further concentrating and crystallising, obtaining a crop of crystals. These, however, consisted largely of sulphate of soda (Glauber's salts), but undoubtedly contained crystals of potash alum.

This method, the principle of which was applied by Newlands many years ago to the recovery of potash from sugar solutions, would be costly to carry out in practice, as it involves first the separation of the silica from the recovered ash; second, the separation of the bulk of the soda from the potash; and finally, the purification of the alum. On the other hand, the advantages of being able to purify the waste lyes, together with the value of the potash recovered would, I dare say, allow of considerable expenditure in dealing with the problem.

#### IV.—Fuel, &c.

It is always an important addition to manufacturing experience to be able to estimate from well-established data the amount of steam or coal consumed in carrying on any manufacture. The difficulties to be overcome in doing this naturally depend on the nature of the operations to be carried out, whether in fact heat is consumed in bringing about chemical reaction, or in the generation of mechanical force by any of the well-known types of steam engines; or in the process of artificial drying or evaporation. All these, namely, heat for—(1) accelerating chemical reaction; (2) for generating mechanical power; and (3) for drying, are used in the preparation of straw cellulose; and the conditions of the manufacture being well defined it is a simple matter to calculate the lowest amount of steam required to perform the various operations in the different departments of a straw pulp factory. It is not my intention to include in this paper the various formulae I employ to ascertain these items, as they more properly belong to another subject, but as this paper would be incomplete without reference to the fuel used to produce a ton of cellulose, I will simply state the results I have obtained by the application of these formulae. It will be convenient to calculate the quantity of steam required for each operation and then to total the amounts.

a. *Steam for Digesting the Straw.*—It is obvious enough that the quantity of steam required to boil straw depends upon the temperature at which the digesting process is conducted, the proportion of caustic lye to straw being in nearly all cases about the same. The higher the pressure or temperature (for the one corresponds to the other) the more heat is required to raise it to that temperature. If therefore, we know the respective weights and specific heats of the caustic lye, straw and boiler (wrought iron) it will be easy to calculate the total heat units required to raise them to the maximum temperature, and as the heating is done with high pressure steam it will not be difficult on the other hand to calculate the weight of steam that is needed to impart this necessary amount of heat. It is on this principle, one which indeed is applicable to a great number of parallel cases and is commonly known, that I ascertain the lowest amount of steam required to boil straw.

\* An allowance of course must be made for the amount of potash present in the straw as a silicate.

To take the individual case above quoted in which a charge of 40 cwt. of straw and 16,915 lbs. of caustic soda lye of 10<sup>15</sup> Tw. were boiled in a wrought-iron boiler weighing 7 tons at a maximum pressure of 60 lbs. above atmosphere (i.e., 307° F.) there were 4,199 lbs. of steam required to raise the boiler and contents to 307° F. This weight of steam represents the lowest amount that can possibly be consumed in performing the work. By a simple proportion sum, the steam needed to digest 49 cwt., or that quantity which produces a ton of cellulose can be ascertained. It is necessary to make an allowance for loss of heat by radiation which invariably takes place, but as this varies in different factories it can only be properly estimated by direct investigation. My own experience, which is somewhat limited in this particular manufacture, is, that an allowance of 20 per cent. is ample for well-arranged works in which the steam boilers are in close proximity to the digestors.

*b. Mechanical Power.*—This is usually generated by a steam engine of the simple condensing, compound, or triple expansion type, and as the steam consumed in the development of one indicated horse power per hour by each of these types of engines is generally known, and can, in any case, be estimated with accuracy, if the total amount of power expressed in horse power required to produce a ton of cellulose be known, the steam necessary for this department can be easily calculated. In well-arranged works, from 3 to 3½ horse power per hour are required per ton of pulp per week. That is to say, a factory producing 30 tons of air-dry pulp per week will require a mechanical power equal to from 90 to 105 indicated horse power generated continuously throughout the week (144 hours). This power includes the cutting and dusting, disintegration of the pulp, and in fact is sufficient to drive the whole machinery of the mill. Assuming a compound engine of modern construction to be used for generating this force, using say 18 lbs. of steam per indicated horse power per hour, then we have

$$\frac{90 \times 18 \times 144}{30} = 7,776 \text{ lbs. of steam per ton cellulose.}$$

*c. Drying.*—To ascertain by calculation, the amount of steam to dry the wet web of pulp is not so simple, although this case is well defined and can be expressed by a formula of very general application. The wet web of pulp which contains about 55 per cent. of water, 50 per cent. of which must be driven off, is passed over a series of drying cylinders heated by steam of from 8 to 10 lbs. pressure. Having regard to the special circumstances prevailing in such a system of drying it may be fairly assumed that the water in the wet web is evaporated as steam of 212° F., and that the water condensed within the cylinders is ejected from them at a temperature corresponding to the steam pressure within, viz.:—8 to 10 lbs. per square inch above atmosphere. The steam condensed within the cylinders is a measure of the water evaporated. If we know the amount of water to be evaporated from the wet web per ton of air-dry cellulose made, it is not difficult to estimate the necessary quantity of steam to perform this evaporation. The water to be driven off, as above indicated, may be fairly taken at one ton (2,240 lbs.) per ton of cellulose, and the quantity of steam condensed to water of temperature 240° F. (10 lbs. steam pressure) inside the cylinders to evaporate this water, i.e., convert it into steam at 212° F. and under atmospheric pressure, is 2,647 lbs. In this, as in the first case mentioned, an allowance must be made for loss of heat by radiation. After carefully considering similar cases and making tests, I have come to the conclusion that 15 per cent. of the calculated quantity is sufficiently large to cover this loss, in all cases where there are few stoppages in the drying, and where the ends of the drying cylinders are protected by non-conducting materials.

Collecting these results we then have per ton of cellulose.

Steam for digesting, including loss of heat by radiation	Lbs.
20 per cent.....	6,613
Steam for developing the mechanical power.....	7,776
Steam for drying, including allowance of 15 per cent....	3,944
Total steam required .....	17,433

To convert this into coal, it is necessary to know how much water is evaporated in the steam boilers per lb. of coal burnt. Assuming this to be 7 lbs. water, the above 17,433 lbs. of steam represents 2479 cwt. of coal. This, according to my observations, is rather lower than that usually used per ton of straw cellulose made, excluding the coal used for soda recovery, but I venture to think it fairly represents what can be done, and is a direct measure of the possibilities in the hands of pulp makers with regard to the economy of coal.

#### DISCUSSION.

Mr. A. SMETHAM said he had been interested personally in the distinctions which Mr. Beveridge drew in regard to the different straws and their value to the paper-maker, and that more particularly because in their use for feeding purposes various straws had distinct values. He noticed in the tables by Müller that the percentage of cellulose was found to vary to a very large extent, whereas with Mr. Beveridge's estimates the percentages for his practical purposes by the bisulphite tests for the cellulose were, if not identical, very nearly so, in the straws from the various sources. It had been puzzling him how to account for those differences. Doubtless in paper-making a certain quantity of the actual cellulose would be destroyed, partly in bleaching, and it might be for those reasons that the differences existed. He was not aware what process Müller used for the estimation of the cellulose, but taking his figures, and assuming for the moment that Müller had used a process which he (Mr. Smetham) thought, was common with nearly all agricultural chemists, viz., that of boiling with 2 per cent. solution of sulphuric acid, washing with water, then boiling with a 2 per cent. solution of caustic potash, washing again with water, then with a dilute cold solution of hydrochloric acid, and washing free from acid, then with alcohol and ether, and finally drying. It seemed difficult to believe that the quantity of cellulose, as stated by Mr. Beveridge, would really be above that in the table, the more especially as he noticed that the strength of the caustic soda used by the paper-maker was something under one-third per cent. It was true that the digestion went on very much longer in paper-making than in the laboratory (for half an hour) with the caustic; in practice, according to Mr. Beveridge's tables, it went on under pressure at a temperature of 307° for four hours, and possibly therefore there might be gradual loss. He imagined that the process in the laboratory would have been quite as drastic as the process of the paper-maker, and it was certain that Müller's results, so far as oat-straw was concerned, were in accordance with what was found when the straw was used for feeding purposes. The percentage of cellulose in straw depended very largely on the period of growth, and it was possible that the differences between Müller and Mr. Beveridge could be accounted for in that manner. Certain it was that the oat-straw was more valuable for feeding purposes than wheat-straw. He would be interested if Mr. Beveridge could throw some light upon that difference, and it would also be interesting to him if Mr. Beveridge would sketch in a rough way the process which he used on the laboratory scale for estimating the cellulose by the bisulphite test.

Mr. BATESON remarked that there was a process brought forward to add bicarbonate of soda and precipitate silica. Was that process likely to pay? The table exhibited showed that the percentage of cellulose varied a great deal, according to the quantity of caustic soda added. What was the reason of this variation? With regard to the recovery of potash in the residual liquors, would not the potash accumulate, and was there not a point where it would be taken away advantageously?

Mr. BEVERIDGE said the fact was the laboratory method which he had used for estimating the cellulose was that formulated by Müller, and did not involve the use of caustic potash at all, but was substantially that indicated in the body of his paper—namely, treating the sample first with water, then, after drying, with alcohol and benzol, and finally with successive baths of ammonia and bromine water,

an allowance being made for mineral matter in the cellulose residue. It was therefore distinct from the method mentioned by Mr. Smetham, which included digesting the sample in a 2 per cent. caustic potash solution, whose solvent action was much greater than that of ammonia. It was five years ago since he (Mr. Beveridge) tried Müller's method, and he confessed he was not so well acquainted now with the details as he ought to be. He threw over the process at that time because he found it did not give him a correct idea of the amount of cellulose available for paper-making, and, as a manufacturer, preferred the bisulphite method instead. This consisted in digesting the straw for six or seven hours in a bisulphite of soda solution containing about 2.75 per cent. total  $\text{SO}_2$ , about 55 per cent. of which existed in the free state, the other 45 per cent. being combined as monosulphite. The temperature employed corresponded to a steam pressure of 60 or 70 lb. above atmosphere. The apparatus he used consisted of a strong tube of antimoual lead inserted in a small wrought-iron boiler containing water. This boiler, which was heated by gas, acted as a steam jacket. The sample and bisulphite solution were placed within the antimoual lead tube. While managing a large sulphite wood-pulp plant on the Thames, where all the pulp boilers were stationary, he had used another and more convenient and reliable method. This consisted in simply placing the sample of straw and the bisulphite solution in a cylindrical leaden dish, sealing it up with the blow-pipe excepting a small pin-hole in the cover, and placing it inside one of the large wood-pulp boilers. The sample was "digested" under the same conditions of time and temperature as the wood within the boilers. In this way he got excellent results. He had varied the percentage of  $\text{SO}_2$  within certain limits, and had found that the yield of cellulose was not affected by a reasonable excess of  $\text{SO}_2$  as bisulphite. The percentage of  $\text{SO}_2$  must not, however, be too high, otherwise he thought hydro-cellulose was formed. These results were uniformly lower than the percentages given by Müller, and if the latter were correct he could not understand why paper-makers did not get a higher yield than 40 per cent. air-dry pulp by the most careful manipulation in the factory.

He believed that some substance was included in Müller's percentages of cellulose as given in the table which could not rank as cellulose. The fact that, in the instance quoted by Roth, in which a yield of 50 per cent. air-dry pulp was obtained, 7 ewt. of bleaching powder were required to bleach 1 ton of this pulp, plainly showed there was some substance present which required inordinate oxidation. He thought on the whole Müller's results were too high. The percentage of cellulose given by Müller for the oat-straw agreed more closely with his own, but that given for wheat and barley was too high according to his experience. Referring to the points raised by Mr. Bateson, the potash could not be allowed to accumulate in the liquors unless the silica was periodically removed. The amount of this silica was so great that where the percentage of soda recovered was anything like 70 per cent. of the amount put into the pulp boilers, after the recovered ash was used twice or thrice it became practically worthless for further use for digesting. It was obvious therefore that the silica must be removed before the potash could be allowed to accumulate to any great extent. The separation of this silica as a practical manufacturing operation was indeed a very difficult process, but if this could be adequately done, the only way, as far as he knew, in which the potash might be utilised was by the method mentioned in the paper, viz., by separating the carbonate of soda from the carbonate of potash by crystallisation, and, after neutralising the mother-liquors with sulphuric acid, adding sulphate of alumina to get a potash alum.

## THE MANUFACTURE OF CALOMEL IN JAPAN.

BY EDWARD DIVERS, M.D., F.R.S.

*Introductory.*—Calomel, in the form common in England and all countries under western civilisation, is now extensively used and is even manufactured in Japan, under the name of *kankō*. But mercurous chloride is also largely used there, under the name of "light powder," *keifun* (Chinese, *kingfun*), in another and very much older form, which is of signal purity, and made by a simple process as yet quite unknown in Europe. I witnessed this interesting process from beginning to end some years ago, and now make this publication of it to the Society, with full permission of the proprietor of the works I visited, Mr. H. Kokubu, who has aided me in every way he could, and notably with drawings, some of which illustrate this paper.

*Historical.*—According to Terajima Hokyō and Ono Ranzan, writers who lived in the last century, the first-named perhaps a little earlier, calomel was known in Japan as far back, at least, as the beginning of the eighth century, having then been presented to the Empress Gen-miyo; but their authority is the *Zoku Nihongi*, reference to which, Professor Haga, F.C.S., informs me, makes it clear that mercury itself, not its chloride, was the thing presented.

In the time of the writers above named, mercurous chloride was well known and was manufactured in Japan, not only at Isawa, a village in Isé, where it is still made, but also in the city of Osaka and in a town near it, called Sakai. Mr. H. Kokubu, manufacturer, tells me that records exist at Isawamura of his family having carried on the manufacture of *keifun* there for the last three hundred years.

Far earlier, namely, in the tenth century, Minamoto-no-Shitagō, in his work entitled *Wamyo-Ruijushō*, makes mention of a mercurial preparation named *kūfun* or "powder of mercury." It is, however, questionable whether this was mercurous chloride or mercuric oxide, and therefore whether calomel was known or not at this time. But since calomel, under the name of *keifun*, is mentioned by Chinese writers even earlier than this, it may be safely accepted that Japanese knowledge of this body is older than ours in Europe. The western knowledge of chloride of mercury dates from the first half of the sixteenth century, but the distinction between calomel and corrosive sublimate was not recognised till near the end of that century.

*Literary.*—The literature on Japanese calomel is meagre. Japanese writers of the old school have contented themselves for the most part with translating Chinese writings. Ono Ranzan mentions that the Japanese method differs from the Chinese in making use of water in place of alum and other chemicals, in which he came near the truth. The late Dr. Geerts, a Dutch pharmacist, who in the Government service did much in establishing Western pharmacy in Japan, treated of *keifun* in some metallurgical contributions he made to the *Transactions of the Asiatic Society of Japan*. What he wrote is contained in Vol. IV. (1875), and consists of information almost exclusively about Chinese calomel, and derived more from Chinese and Japanese writings than from any experience of his own. Concerning Chinese calomel English readers have the *Notes on Chinese Materia Medica*, among the "Science Papers" by the late Daniel Hanbury, F.R.S., edited by J. Ince. Hanbury mentions as the result of his own observation, the characters of *kingfun* and its great purity but for the presence of minute, transparent, acicular crystals of calcium sulphate. He refers to Porter Smith's *Contributions towards the Materia Medica and Natural History of China* for an account of the manufacture. Smith, however, takes his information solely from Pearson's account on p. 59, Vol. III. of Sir J. Davis's work *On the Chinese*. I have not seen this book, but it is clear from Porter Smith that Pearson, again, has only derived his information from the Chinese *Materia Medica*, *Pun-tsau-kang-muh*, and not from his own observation, and it amounts to this:—Common salt and mercury, of each 1 oz.; alum, 2 oz.; or salt, mercury, copperas, and saltpetre, in some

such proportions, are rubbed together and put into an iron bowl, which is then covered with a roomy earthen dish well luted down. This is exposed to the heat of a strong charcoal fire for four or five hours, when water is thrown on the cover and the cover taken off. On its inner surface the calomel is found adhering in the form of a beautiful, feathery, white sublimate. Ten parts of mercury are said to yield about eight parts of calomel. Dr. Geerts's paper, already referred to, contains essentially the same account, translated from the Japanese version of the Chinese work.

Lastly, there is a paper, in the Japanese language, on the manufacture of *keifun* at Isé, which is the forerunner of the present one. That paper appeared in 1887 in the *Journal of the Tôkyô Chemical Society*, written by Mr. T. Shimidzu, M.E., F.C.S., my former pupil and colleague, and it was his description to me of what he had seen that led to my own visit to Isé in company with Professor Haga in the following year. In one or two points I have availed myself of this paper to make my own account more complete.

**Of the Specific Properties of Keifun.**—*Keifun* is in very thin minute scales, lustrous, transparent, and white or faintly cream-coloured. It might be described as micaceous calomel. To the touch it is soft and smooth. Measured in bulk, dry, it is four times as voluminous, more or less, as the ground calomel prepared by the European process, and can be readily scattered by a puff of the breath. Rubbed hard in a porcelain mortar it gives the brown resinous streak characteristic of calomel, and the evidence therefore, according to pharmaceutical authorities, of its freedom from corrosive sublimate. Exposed to bright sunlight it gradually assumes a light brown colour, a colour, that is, having no affinity to grey or black. Moisture does not seem to favour this change, which is certainly not owing to any reduction to metal. European calomel suffers a similar change. *Keifun* is free from corrosive sublimate and from metallic mercury.

Hanbury found selenite in Chinese calomel, and Geerts found calomel of this form generally adulterated with selenite and mica, but whether what he examined was ever Japanese and not always imported Chinese calomel he does not show. I have found *keifun* as it came direct from Isé quite free from adulteration, and have not met with any adulterated.

#### *Of the Materials used in making Calomel in Isé, Japan.*

—The materials for making Japanese calomel are: mercury, an arenaceous red clayey earth, bay-salt, bittern or salt-mothers, and air. The mercury is imported from Europe, but in old times is said to have been found in the neighbourhood of Isé, as cinnabar.

The earth, called *mitsuchi* ("seed-earth"), is all taken from a neighbouring hill, Shunakayama, and, according to Mr. Kokubu, many other clays have been tried in place of it, always with bad results. It is of a rather light bright red colour, which changes to a duller and somewhat brown red on drying and gently heating the earth, and to a light ordinary brick red by a strong heat. As mined, the earth is seen to consist largely of colourless quartz grains. Besides the quartz a very little biotite is seen sparkling through it. The fresh damp earth does not form a compact mass, but a slightly cohering aggregate of damp crumbs. This texture appears to be due to the earth being a mass of quartz in small grains from the size of a hempseed down to that of impalpable particles, held together by plastic clay. For use, that which does not contain coarse quartz grains too abundantly is selected, and is made into briquettes and moderately baked on the hearth of the fire-place under the calomel pots. These briquettes are then as light and porous as the prepared porous clay used in Fletcher's gas-furnaces. The raw earth, air-dried, is readily rubbed into its constituents by the fingers; and the baked briquettes very easily and rapidly reduced to a soft powder, quartz grains and all, in the agate mortar. The larger grains of quartz in the raw earth are also very brittle. I have treated thus fully of the mechanical characters of the earth, because probably much of its efficiency is due to them. But its chemical character also calls for notice. As baked ready for use it contains in the thoroughly air-dry

condition still 5 per cent and more of water. Before ignition it is almost entirely decomposed by sulphuric acid, either in some days in the cold or quickly by heat. It is also largely acted upon by hot hydrochloric acid, and heated in sealed tubes with this acid to 120–150°, it is almost as fully decomposed as by sulphuric acid. It contains practically no silica soluble in hot sodium carbonate solution, but after acid treatment yields, of course, much silica to this reagent. The composition of the earth, as found in use at the works, but rendered anhydrous, is as follows:—

Quartz .....	58.1
Combined silica .....	24.2
Alumina .....	20.4
Ferric oxide .....	10.5
Magnesia .....	0.3
	107

The magnesia is only got by fusion of the finely-ground earth with alkali carbonate, and belongs to the particles of mica scattered through it. Only doubtful traces of phosphoric acid could be found, and, what is specially to be noted, no lime whatever. The earth is thus nothing but quartz, kaolin, ferric hydroxide, and a very little biotite, and is probably valuable to the calomel maker not only for its highly porous texture, but also for its negative chemical qualities.

The bittern and even the rough bay-salt contain magnesium chloride, and this rather than sodium chloride must be the source of hydrochloric acid in the process. That air finds a graduated entrance to the other materials by diffusion during the process, will become evident from a consideration of the set-up of the apparatus.

**Of the Plant.**—The apparatus for making Japanese calomel consists of a table furnace supporting 60 cast-iron pots lined and surmounted with the Shunakayama earth or *mitsuchi*, on which rest, as covers and condensers and receivers of the calomel, unglazed clay cups bottom upwards.

In Fig. 1 the furnace as it is when in action is seen from the working side; 10 pots on the left side are shown still to be charged and covered. The wooden step in front is

Fig. 1.

to enable the workman to reach over the table easily when charging the pots or emptying them. In Fig. 2 the furnace is seen from the back or firing side, and with the walls broken away to show its interior and the method of firing. In Fig. 3 the mounting of the pots is shown in three stages by sectional plans of the table.

On a smoothed clay hearth the walls of the furnace are raised in clay, building in the three stones which frame the stove-hole (Fig. 3). The walls are 2.6 ft. high and the enclosure is 7.6 ft. by 4.7 ft., measured outside. The

stoke-hole is 1 ft. by 1 ft., but a little wider than this at the base, and is without door. The table of pots and roof of the furnace is constructed (Figs. 1 and 3) by laying a square iron rod on each of the long walls, and on these 11 cross rods, also square, on which are to rest the flanges of the pots. The pots are then put in position as close

Fig. 2.

together as possible, hanging by their flanges, in 10 rows of six each, and plastic clay pressed into the openings left between the flanges and the roots, and the roots and flanges covered in so that only the mouths of the pots remain visible, as shown by the middle rows in Fig. 3. The furnace clay being thoroughly dry it is deeply laid over

Fig. 3.

with the red earth mixed with a little bay-salt and moistened with bittorn in small quantity. The pots are also filled with the same moist red earth, except in a central cylindrical shaft (see the left side of the furnace-table in Fig. 1 or the right side in Fig. 3), reaching to the bottom of the pot which is left bare. The pot is 0.5 ft. deep inside, and across its mouth, inside, is 0.45 ft. It is shown in Fig. 4. The shaft or cavity left in the filling is 0.18 ft. in diameter, and is shaped by resting a wooden core on the bottom of the empty pot, and then pressing in the moist earth round it, smoothing off the top, and dropping a perforated board over the projecting core to hold down the earth while withdrawing the core, which is then removed by its handle. The furnace is now ready for work. It should have been mentioned that after the clay walls of the furnace are built they are framed in with wood to increase their stability and to give support to a wooden back and to shelving above the table, as seen in Fig. 1.

**Of the Firing.**—The firing the pots is kept far below what are usually regarded as furnace heats. The fuel employed is wood, and the Japanese are clever in the use of this economically and effectively in firing pots for boiling, evaporating, distilling, or subliming. The method of heating is seen in Fig. 2. Five lengths of firewood are ranged

along the back and front walls on the hearth, generally raised at one end by resting on a lump of clay. In the ordinary working of the furnace, as I saw it, the heat from previous work is sufficient to kindle the fresh wood. The flames rise up the sides and run over the bottoms of the pots, leaving the central space in the chamber free from flame. The air enters by the lower part of the stokehole and the products of combustion escape invisible by its upper part, so perfect is the combustion. At the time of

Fig. 4.

- f. Wooden core and board for lining pots.
- g. Bamboo water pot for wetting furnace top.
- h. Quill feather for emptying cups.
- i. Ped for lifting compost ball out of pot.

first lighting the fire, and of irregularities in stoking, some smoke is unavoidable, and to keep the top and table free from this smoke and from ashes, a wooden back is put in above the table, as shown in the figures. There is also a wooden hood and flue above the stokehole to carry off any smoke: this is not shown in the figures, but is similar to those put up in England and elsewhere over the working doors of furnaces to protect the workman from arsenic, sulphur, or other noxious fumes. The heating is so well effected that the pots two feet above the burning logs are made sufficiently hot, barely red-hot at the bottom, and yet the wooden frame on the outside of the furnace is not charred, and the workroom is not unpleasantly warmed.

About three bundles, or 40 lb., of wood serve for one firing, and it is remarkable to see so little fuel working so many pots.

**Of the Working.**—A compost of burnt *mitsuchi* with about a fourth of its weight of bay salt is made up with bittorn into lumps the size of large chestnuts.

The furnace being hot enough, the *mitsuchi* surface of the table is once for all freely wetted by a watering-pot, perhaps half a gallon of water being used, all of which is absorbed; a lump or two of compost is dropped, by tongs or by hand, into each pot in rapid succession, a very small

spoonful of mercury poured into each pot, the total charge for the 60 pots being somewhat less than one pound avoirdupois (more exactly,  $\frac{5}{8}$ th of a lb.), and a clay cup, bottom up, placed over each pot and adjusted by gently pressing and turning it round slightly. The cup is thus made to fit neatly on the earthen top without adhering to it in the least. The cups are thick and unglazed, but become very smooth inside by use. They have an inside diameter at the mouth of 6 ins. and a depth of 3 ins.

Thus arranged, the pots and cups are left for three hours, and during the latter part of this time the furnace is cooling. When cool enough, each cup is lifted in turn, and, with two turns of a feather, the *keifun* or calomel, which fills it in the form of a sparkling network of delicate crystalline scales, is transferred to a sheet of paper held under it, and the cup mouth downwards placed on a shelf of the furnace ready for use in the next operation.

The calomel, it will thus be seen, forms no adherent cake in the cup, but particles only loosely hanging together. So obtained, it is ready for the market, needing only to be packed in small wooden boxes for sale.

The spent lumps of earth and salt are lifted out of the pots by the tool shown in Fig. 4, and when the furnace has become still cooler, the fire is made up again, the furnace top freely wetted, and a new operation set going as before. The furnace is worked twice each day. Nothing could well be carried out with great simplicity and less expenditure of labour and time.

*Of the Yield.*—The loss, I am told, is about 16 per cent. of the theoretical amount of calomel, which is, I believe, about twice as much as is lost in the Western process.

*Experimental.*—If one of the cups is removed a few minutes after the operation has been started, much of the mercury is found in it as a sublimate of fine globules, mixed with only a little almost amorphous calomel, from which it would appear that the formation of the calomel results from reaction in the cup between the mercury in vapour and the active gases.

On dipping into the pot, uncovered during the process, a glass rod with a drop of water hanging to it and then withdrawing it, and testing the remainder of the water with potassium iodide and starch, no chlorine can thus be detected. The same is true when a drop of solution of potassium hydroxide is used. Nor can the slightest odour of chlorine be detected in the vapours issuing from the uncovered pot.

On passing air containing a little hydrochloric acid gas through a tube in which mercury is freely boiling, sparkling calomel is formed close to and mixed up with the mercury.

Red earth which has been used in the process turns moist red litmus paper blue, while fresh red earth is neutral.

*Theoretical.*—The nature of the materials used and the observations gained by the preceding experiments are sufficient to establish that the calomel is formed by a reaction between mercury vapour, oxygen, and hydrochloric acid gas, in which along with mercurous chloride, water is formed— $4\text{Hg} + 4\text{HCl} + \text{O}_2 = 4\text{HgCl} + 2\text{H}_2\text{O}$ , and that the formation takes place at a temperature near—above or below—the boiling-point of mercury, and much below that at which calomel freely volatilises. The source of the hydrochloric acid is certainly the magnesium chloride of the bittern and bay-salt, which heated in a moist atmosphere, even in the presence of sodium chloride, is as well-known partly converted into magnesia and hydrochloric acid. Hence the alkalinity of used *mitsuchi*.

The porosity of the walls of the apparatus, particularly of the layer of *mitsuchi* on which the clay cup rests, must be more than sufficient to allow enough air to enter during the working. I had supposed that the hot hydrochloric acid and air might, in contact with the earth, have yielded a little chlorine, but the temperature reached in the process normally worked seems never to reach that required for the liberation of chlorine.

The Chinese process, if correctly described, differs from that used in Japan in several material points, one of which is that the mercury is intimately ground up with the other materials, and one fails to see what reaction can take place between it and the two others, namely, salt and alum. Heated, the mixture must give off mercury and hydrochloric acid,

and then these, as in the Japanese process, will with air give the calomel, but this is independent of the previous intimate mixture of the mercury with the salt and the alum. Another point is that in place of the magnesium chloride of sea water as the source of hydrochloric acid, the Chinese are said to use alum or copperas, which, with the salt, will react to give hydrochloric acid. A third point is that the cover is said to be closely luted to the iron pot, which must nearly exclude the air, without which it is impossible to explain the formation of the calomel. Perhaps this is the reason why the Chinese process is said to take four or five hours firing, since this may give time enough for the needed oxygen to diffuse through the cup and lining, it will also account for the fact, if it is one, that the yield of calomel is markedly less in weight than the mercury used. Again, there are to be noticed the statements that the iron pot is exposed for hours to the strong heat of a charcoal fire, and that the hot clay cover is cooled by throwing cold water on it, statements which must be regarded as greatly exaggerated, if not erroneous. Lastly, the calomel-giving vapours are allowed to remain in contact with the hot iron of the pot, instead of being kept from it by the thick lining of earth provided in the Japanese process, a contact which such vapours could not stand without destruction. I think, therefore, that we may be fairly doubtful whether any reliable description has yet been given concerning the Chinese process, which we may expect to find to differ little, if at all, from the Japanese process, except in salt and alum being used in place of the mother-liquor of sea-salt or "water," as Ono Ranzan supposed it to be.

One thing to which attention may be called is that the Chinese are stated to add some nitre to a similar mixture when employed to give corrosive sublimate. For that being the case, it is seen that free chlorine, which would here be developed from the salt, nitre, and alum, is necessary for the production of the higher chloride, and that air and hydrochloric acid can only yield the lower chloride, a difference of much theoretical interest, and indeed of practical moment also. It is known that re-sublimation of calomel generates some corrosive sublimate, and, although authorities are not quite agreed as to whether reaction occurs between gold leaf and calomel vapour, it is hardly to be doubted that such reaction does occur. Now I have found that if in the Japanese apparatus the temperature of the cover be raised sufficiently to volatilise much of the calomel the remaining calomel is no longer free from corrosive sublimate. It must, therefore, be borne in mind that the calomel formed in the Japanese process is not, and cannot be, the result of true sublimation, but of precipitation as fast as formed from the three gaseous bodies which give rise to it. At the temperature at which mercury boils, calomel is either quite fixed or, at most, has a vapour of exceedingly small tension. In the two facts, that the three gases do not react to yield corrosive sublimate and that the calomel is not heated to its volatilising point, lie the explanation and, at the same time, the assurance that Japanese (and Chinese) calomel contains no corrosive sublimate.

*Summary.*—The Japanese prepare calomel pure, above all things free from corrosive sublimate. They heat balls of porous earth and salt soaked in bittern along with mercury, in iron pots lined with earth. The heat forms hydrochloric acid from the magnesium chloride in the bittern, and the mercury sublimes into the closely-fitting but unattached clay covers of the pots. Air enters by diffusion and oxygen and hydrochloric acid gas act together in the hollow cover on the vapour given off from the sublimate of mercury there formed. The cover thus becomes filled with a network of micaceous particles of calomel, precipitated at a temperature below its subliming point at the moment of its formation.

This investigation of an interesting product of Japanese industry has been carried out under the authority of the Imperial University of Japan. I cannot acknowledge fully enough the indispensable assistance I have received from my colleague, Assistant-Professor Haga, F.C.S.

# A REVIEW OF SOME OF THE METHODS IN GENERAL USE FOR THE ESTIMATION OF MANGANESE IN MINERALS AND METALS.

BY E. H. SANITER, F.C.S.

THE quantity of manganese ores, spiegeleisen and ferro-manganese sold in this and other countries is very considerable, the price being based on the actual content of manganese present.

As the results of analyses by different chemists vary somewhat considerably when operating on the same sample, I have considered the question to be of sufficient importance to devote a considerable amount of my time to ascertain the relative merits of the various known methods which are at the present time in general use.

I believe it is a fact that in England the process most generally used is that of Mr. Pattinson, or a modification of it used by Mr. Riley, in which carbonate of lime is replaced by zinc oxide.

On the Continent the volumetric process of Volhard is extensively used.

In America, according to Blair, the gravimetric process, in which the manganese is weighed as pyrophosphate, is considered to be the most accurate.

The gravimetric method, in which the manganese is weighed as  $Mn_3O_4$ , is, I believe, used more or less in all countries.

My first object was to obtain a substance containing a known quantity of manganese.

The manganic-manganic oxide, which, I believe, is generally used, is not to be relied upon unless very extraordinary precautions are taken in its preparation.

I have found it impossible to obtain it with the theoretical percentage of 72.05 per cent. of manganese, when all that metal exists as  $Mn_3O_4$ .

The following table gives the complete analyses of precipitates prepared by different processes.

These analyses have been conducted with the utmost care.

TABLE I.

Batch No .....	1.	2.	3.	4.
Mn <sub>3</sub> O <sub>4</sub> .....	Per Cent. 97.85	Per Cent. 99.51	Per Cent. 99.70	Per Cent. 99.788
Excess of O.....	0.03	0.13	0.05	0.020
MgO.....	0.16	0.04	0.03	0.016
CuO.....	0.75	0.05	0.14	0.125
SiO <sub>2</sub> .....	0.60	0.24	0.02	0.006
Fe <sub>2</sub> O <sub>3</sub> .....	0.25	Nil	0.04	0.045
NaO and Co.....	0.22	0.3	0.02	
CuO.....	0.14			
	100.00	100.00	100.00	100.00
Manganese.....	70.5	71.69	71.83	71.90
Bracketed impurities ...	1.21	0.27	0.08	0.051

The bracketed impurities are those which would be in part removed by Riley's after-treatment referred to later on.

The  $Mn_3O_4$  is taken by difference.

No. 1 batch consists of  $Mn_3O_4$  precipitates produced in the analysis of ferromanganese by the gravimetric method without after treatment of the precipitate.

No. 2 batch. A pure solution of manganese chloride was prepared from 84 per cent. ferromanganese by the careful separations of Si, Fe, Ni, Co, Cu. The manganese was then precipitated with bromine and ammonia in a glass flask, the resulting precipitate being converted into  $Mn_3O_4$  by calcination. The largest impurity is silica, dissolved from the flask by ammonia.

Nos. 3 and 4. These batches were prepared from a pure solution of manganese by precipitating in the cold with carbonate of ammonia in a porcelain dish, the precipitate

being subsequently calcined. It would be an improvement to precipitate the manganese as sulphide with sulphide of ammonium instead of carbonate, by this means separating the lime and magnesia. The sulphide of manganese is then converted into  $Mn_3O_4$  by calcination.

Having now obtained a quantity of manganomanganic oxide containing known percentages of manganese, the next step was to carefully estimate the manganese in each of the samples of  $Mn_3O_4$  given in Table I. by the four methods, the accuracy of which it was proposed to investigate.

The results of these analyses are given in the table at the bottom of previous page.

Results marked A are by my assistant and B by myself. Ashless filter-papers have been used and every possible precaution taken to ensure accuracy, the burettes being calibrated, and dichromate solution standardised on two different specimens of "pure iron," both of which had been completely analysed for impurities, the one being that used by Mr. Stead, of Middlesbrough, for this purpose; the other, that which I have always used myself, and which corresponds exactly with that of Mr. Stead.

In reviewing the results given in this table, I propose to consider each method separately as to its general usefulness and as to its accuracy, by comparing the results obtained by it with the actual percentage of manganese given in the first column.

**Estimation as  $Mn_3O_4$ .**—The ordinary method of conducting this operation, is, after separating the silica and iron &c. with ammonia and ammonium acetate, redissolving, and reprecipitating, to precipitate the manganese in the filtrate with bromine and ammonia, small quantities of Ni, Co, and Cu, not being previously separated, boil, filter, wash, dry, and calcine the precipitate at an almost white heat to  $Mn_3O_4$ , weigh.

From the weight thus obtained, reckoned as pure  $Mn_3O_4$ , the percentage of manganese is calculated.

In order to ascertain what amount of error was introduced by this procedure, an average lot of about 20 precipitates, obtained in estimating ferromanganese, similar to that shown in Table IV., were ground up together, and analysed for impurities as shown in Table III.

TABLE III.

ANALYSIS OF  $Mn_3O_4$  PRECIPITATES.

$Mn_3O_4$ .....	99.09 per cent. = 71.4 per cent. manganese.
Excess of oxygen .....	0.02 "
Silica .....	0.21 "
Peroxide of iron .....	0.05 "
NiO and CoO.....	0.22 "
CuO.....	0.14 "
Ag.....	0.16 "
FeO.....	0.07 "
	100.00

After making the necessary allowance for filter-ash, the precipitates contained only 71.4 per cent. Mn. against a theoretical 72.05 per cent., thus showing an excess of 0.91 part on the 100 parts of manganese present, when assuming these precipitates to be pure  $Mn_3O_4$ .

It should, however, be stated that many chemists, after weighing the  $Mn_3O_4$  precipitate, dissolve it in hydrochloric acid, and separate the  $SiO_2$ ,  $Fe_2O_3$ ,  $NiO$ ,  $CoO$ , and  $CuO$ , the combined weight of which is deducted from the original weight of the  $Mn_3O_4$  ppt. before calculating. This procedure considerably reduces the error, but still leaves that due to lime and magnesia. When the method is applied to estimation of manganese in manganese ores where much lime, magnesia, and baryta are present, this source of error becomes very serious, and may be as much as 1 to 2 per cent.

The bracketed impurities in Tables I. and III. are those which are removed by this after-treatment of the precipitate.

As a check on Table III., showing impurities in  $Mn_3O_4$  precipitates, a sample of ferromanganese was subjected to complete analysis, the manganese being estimated as already described and calculated, taking the precipitate as pure  $Mn_3O_4$ ; also with the correction shown to be necessary in Table III.

The result is given in Table IV.; the totals obtained confirm the analysis in Table III.

TABLE IV.

## COMPLETE ANALYSIS OF FERROMANGANESE.

	Per Cent. Stead's Tables as usual.	Per Cent. 81.27% Corrected by Table III.	Per Cent. 81.19% By Pottal son's method, corrected by Table II.
Mn	100.00	100.00	
Fe	0.20	0.20	
Cu	0.20	0.20	
Ni, Co	0.20	0.20	
C	0.79	0.79	
Si	0.65	0.65	
P	0.23	0.23	
	100.65	100.94	

Even when this process is worked with every possible care, all metals, except manganese, being separated, the use of a glass vessel for precipitation contaminates the precipitate with a considerable amount of impurities, as shown by Batch 2, Table I., which only contains 71.69 per cent. of manganese and is prepared in this way, a quarter per cent. of silica being taken up from the glass.

**Low results** are also obtained from several causes, the chief of which is the presence of ammonia salts in the  $MnO_2$  precipitate when being calcined, which gives rise to a deficiency of oxygen and in some cases a volatilisation of manganese. In order to demonstrate this, two precipitates of equal weight of hydrated  $MnO_2$  were calcined, the one being washed, the other unwashed, and containing a large quantity of acetate, chloride, and bromide of ammonia, with the following result:—

	Washed.	Unwashed.
	Grm.	Grm.
Weight after calcination .....	0.568	0.482

A deficiency of 0.086 gm. on the unwashed.

In order to determine the extent to which the O in  $Mn_3O_4$  varies, a considerable number of precipitates were tested for O in excess of  $MnO$ , and the O was found to vary between 4.0 and 7.2 per cent., thus confirming the results obtained by previous investigators. *This source of error, alone, condemns the method;* the low oxygen results being attributable in part to the too rapid heating of the oxide in the presence of ammoniacal organic salts.

**A Modification of the  $Mn_3O_4$  Method.**—If after the separation of all other metals from the solution of manganese, the manganese is precipitated with ammonium sulphide, filtered and washed, as directed by Fresenius (Quant. Anal. Vol. 1. p. 204), and the precipitate calcined, very strongly nearly pure  $Mn_3O_4$  is obtained.

The  $Mn_3O_4$  results in Table II., Batch 4, were obtained in this manner, and are fairly accurate.

The precipitates obtained by this method are less likely to vary in their percentage of oxygen, as their physical condition is fine and porous. Both precipitates were tested and showed 6.97 per cent. of oxygen in excess of  $MnO$  and no sulphur.

The solubility of the sulphide precipitate seems to be very slight, the filtrate being examined and containing respectively 0.3 and 0.4 mgrm. of manganese, which was added to the result.

**The Pyro-Phosphate Method.**—This method when properly conducted is generally conceded to be the most accurate process for the estimation of manganese, and this is borne out by the results shown in Table II.

The directions given by Blair (*Anal. of Iron and Steel*), if strictly adhered to, give good results. There is, however, one point in which I think a slight improvement might be made.

After the separation of all other metals, there appear to be small quantities of lime and magnesia along with the manganese, even when working on spiegel or ferromanganese, as shown by analyses in Table I., Batches 3 and 4, which were precipitated as carbonate from this solution.

The lime and magnesia probably accumulate from vessels and reagents used during the numerous previous operations.

In order to separate this lime and magnesia, the manganese should be precipitated as sulphide, as previously described, and, after washing, be dissolved through the filter with hot hydrochloric acid and washed with hot water, the filtrate being collected in a platinum or porcelain basin, the former preferably, for precipitation as phosphate. The most important points in Blair's description, and points which cannot be too strongly insisted upon, are:—

(i.) The crystalline state of the precipitate. (I have obtained results 5 per cent. too low through inattention to this point.)

(ii.) The washing with cold ammoniacal solution of nitrate by ammonia. Hot water should not be used as it dissolves the precipitate and causes low results.

*Volhard's Volumetric Method.*—This method depends on the precipitation of manganese from a slightly acid solution by permanganate of potash, as shown by the following equation:—

I have used it as follows:—A quantity of the substance equivalent to 0.4 gram. of manganese is dissolved in hydrochloric acid.

Separate iron and chromium, if present, with ammonia and ammonium acetate and precipitate manganese with bromine and ammonia.

After ignition this precipitate is dissolved in hydrochloric acid and neutralised with zinc oxide suspended in water, any excess being dissolved by adding nitric acid drop by drop.

The solution is then diluted to about one litre with boiling water and titrated with a solution of permanganate of potash until a permanent pink colour is obtained.

The solution of permanganate is carefully standardised against pure iron or a solution of ferrous sulphate of known strength. From the figures thus obtained the percentage of manganese is calculated. On referring to Table II. it will be seen that the results obtained only indicate 99.5 per cent. of the manganese.

This points very forcibly to the necessity of standardising the permanganate solution with oxide of manganese of known composition, instead of, as generally recommended, against iron, as there is always a doubt as to the precipitate being absolutely all  $\text{MnO}_2$ .

The results obtained on Batch 1, Table II., show that small quantities of nickel and copper do not affect its accuracy.

*Pattinson's volumetric method*, which depends on the precipitation of the manganese as  $\text{MnO}_2$  and its titration with ferrous sulphate, is fully described in Mr. Pattinson's paper on "The Determination of Manganese" (this Journal, Vol. XI., p. 336), and in using it the instructions there given have been exactly followed out.

On referring to the results obtained by it in Table II. it will be seen that they only show about 99 per cent. of the manganese present.

Looking at the fact that this method is very largely used, and that Mr. Pattinson says in his recent paper that he always obtains results showing 100 per cent. of the manganese present, I thought it desirable to obtain further evidence as to the accuracy attainable by it. I therefore sent out portions of No. 4 batch of oxide, sufficient for duplicate estimations, to five experienced chemists all accustomed to use this process for the estimation of manganese.

The following are the results, including those of my assistant and self:—

#### NO. 4 BATCH OF OXIDE, CONTAINING 71.9 PER CENT. OF MANGANESE.

No. 1....72.08 per cent. = 100.25 per cent. of manganese present.

" 2....71.93	" = 100.04	"	"	"
" 3....71.26	" = 99.11	"	"	"
" 4....71.22	" = 99.06	"	"	"
" 5....71.20	" = 99.03	"	"	"
" 6....71.15	" = 98.96	"	"	"
" 7....71.03	" = 98.79	"	"	"

The first two results confirm Mr. Pattinson's experience; the other five agree in indicating only about 99 per cent. of the manganese present.

These results show that on the same sample different chemists find considerable variations, due to this method. I find, however, that the results obtained are constant, even if low, when the method is worked by one person under the same conditions.

The results obtained on impure oxide, Batch 1, Table II., agree with Mr. Pattinson's conclusion that small quantities of copper and nickel do not materially affect its accuracy.

I have tried the modification of this method, in which carbonate of lime is replaced by zinc oxide, and find that it is very uncertain in its results, but when the precipitate is submitted to a very much more thorough washing than is necessary with  $\text{CaCO}_3$  the results are the same. Much excess of  $\text{ZnO}$  should be avoided.

*The above facts show the absolute necessity for every chemist, using this method, to carefully standardise his working on manganese oxide of known composition, and to use the factor thus obtained in calculating his results.*

*General Conclusions.*—The weighing of manganese as  $\text{Mn}_2\text{O}_3$  is utterly unreliable if precipitated as  $\text{MnO}_2$ , but is somewhat better when precipitated as  $\text{MnS}$ .

The weighing as pyrophosphate is accurate if the solution is absolutely free from other metals; the numerous operations necessary render this very tedious.

The volumetric methods of Pattinson and Volhard have a tendency to give low results in the hands of many chemists, and if used should be carefully standardised on manganese oxide of known composition at frequent intervals. Thus standardised they are accurate and more rapid than the gravimetric methods.

I cannot close this paper without acknowledging the hints as to procedure derived from Mr. Pattinson's recent paper on the "Estimation of Manganese," and also recording my thanks to my assistant, Mr. Byrom, for the careful manner in which he has checked my results.

#### DISCUSSION.

Messrs. J. and H. PATTINSON wrote as follows:—

"Through the kindness of Mr. Saniter, some ten days ago we saw a rough draft of his paper. We have not a copy by us, and we do not know how much he may have modified it, but speaking generally we conclude that the gist of his paper, so far as regards Pattinson's process for testing manganese, may be summed up in two statements—1st, that in Mr. Saniter's and some other chemists' hands, this process does not indicate the total amount of manganese present; and 2nd that, when using Pattinson's process, every chemist ought to check it against a compound of manganese of known composition, so as to determine in this way a coefficient by which to correct the result obtained by Pattinson's method."

"We regret that Mr. Saniter did not point out to us sooner the differences between his working of the process and ours, for we believe that these differences will be found to be caused by some easily adjusted differences in the reagents or instruments used, or in the manner of carrying out the process, and not by any fundamental error inherent in the process. We feel convinced that this method, in the hands of any moderately skilled chemist, should indicate 100 per cent. of the manganese present. We are told by Mr. Saniter that in testing manganese ores he invariably obtains

a lower result than we do ourselves, and he says that several other chemists' results confirm those obtained by him. On the other hand, during the last 15 years that we have used this process, we have had a large number of instances to show that other chemists of undoubted standing can obtain the same results by it as we do. This method was also examined by Dr. C. R. A. Wright with Mr. Menke (see *Jour. of the Chem. Soc.*, Vol. XXXVII., pp. 22 and 19), and by Professor Ledebur (*Chemiker Zeitung*, Vol. VIII., pp. 910, 927, and 963; *Jour. of the Iron and Steel Institute*, 1884, No. 1, p. 269) and found by them to give correct results. We may add that we have recently had an opportunity of checking the method in the case of two samples of manganese ore analysed by Professor Fresenius, who determined the manganese by the gravimetric method described in the second volume of the sixth German edition of his "Quantitative Analysis," p. 390, and in one case the percentage of manganese found by us was 0.01 per cent. higher and in the other case 0.02 per cent. higher than that found by Fresenius; that is, in both cases the results are practically identical."

"With regard to Mr. Saniter's recommendation that each chemist should check the method for himself with some pure compound of manganese or some compound of manganese in which all the impurities have been estimated with a view to determining the correction that requires to be made upon his particular method of working our process, we think that this would lead to still greater differences amongst chemists than now exist owing to the very great difficulty there is in making pure compounds of manganese, or in estimating small quantities of impurities in them."

"We are sorry that we have not had an opportunity of testing any of the preparations of manganomanganic oxide ( $Mn_2O_4$ ) made by Mr. Saniter, but Mr. Stead, of Middlesbrough has tested both some of Mr. Saniter's preparation of this oxide and some made by us, and in both cases he found the theoretical yield of manganese to be given by Pattinson's process."

"We trust that we may have an opportunity of comparing our methods of working with Mr. Saniter's methods more thoroughly than we have yet done, when we have no doubt but that some simple explanation will be found to show why he gets lower results by this method than we do."

Mr. G. WATSON GRAY thanked Mr. Saniter for having brought his experience before them. Although Liverpool was not a centre where much steel was dealt with, yet manganese was used in the district, and therefore had a certain amount of claim on their attention. The estimation of manganese by precipitating with ammonia and bromine was of course very long and tedious an estimation generally occupying a couple of days. In addition to the many impurities that required removing from the precipitate in order to arrive at a correct result, Messrs. Pattinson have pointed out in the *Journal* that when the method is used it ought to be supplemented by estimating the amount of peroxide of manganese present, and thereby arrive at the correct amount of oxygen contained in the ignited precipitate, for it is not always  $Mn_2O_4$ . They have shown in their paper what a good many chemists knew—that a great deal depended upon the thickness of the platinum crucible, along with the time and other conditions of heating, whether it be a bright or dull red or a white heat, and many more apparently trifling things. The thickness of the platinum crucible might seem strange to some, but Messrs. Pattinson's experience only confirmed what other chemists have observed. The pyrophosphate or the second method dealt with by Mr. Saniter had always given high results in the speaker's hands. It certainly seemed to be the method used in the States, where they always managed to find more manganese in a sample than is done in England. Volhard's permanganate method had the disadvantage of requiring the permanganate to be standardised daily, in addition to many other minor points of an objectionable character, and he did not wonder that Mr. Saniter found a higher percentage of manganese than when using the Pattinson method. Messrs. Pattinson's method had always given within 0.1 of 100; it may have exceeded 100, as already shown by Mr. Saniter, and in other cases it might be 0.1 below 100. He thought that a good many of the other faults that had

been found with the use of the method were due to chemists not taking due note of the details. If Mr. Saniter worked out Pattinson's modified method, published in the *Journal*, using a small amount of chloride of zinc along with the ferric chloride, he would doubtless find 100, if he has been getting a low result by neglecting the addition of zinc chloride, because the latter seemed to have the advantage of preventing the formation of permanganates. Using oxide of zinc as the precipitant in place of carbonate of lime was objectionable, as the chlorine was thereby very difficult to wash out. Mr. Pattinson originally tried it years ago when he first brought the method out. Some one on the Continent suggested the use of zinc, and probably that accounted for Mr. Riley adopting it. Probably in some cases the burettes had not been correct, as a good many were slightly out in the graduations, and when they came to 100 per cent. a little went a long way. In the preparation of pure oxide he could quite endorse what Mr. Saniter had said. It was very difficult to prepare a pure compound, and for that reason he would agree with Messrs. Pattinson in recommending that chemists do not start to make their own corrections for bad workmanship, because those who had prepared the pure oxide knew how very hard it was to obtain anything like purity.

Dr. KOHN asked whether Mr. Saniter had any direct evidence of the volatilisation of manganese in the presence of ammonium salts when it was ignited as manganomanganic oxide, as mentioned in the paper? Also, had Mr. Saniter tried the electrolytic method for the separation of the manganese, since it occurred to him (Dr. Kohn) that that might be an advantageous method for the separation of the manganese previous to its final determination on account of the freedom of the separated manganese peroxide from impurities, such as silica?

Dr. HURTER asked what was the value of one unit of manganese in ferromanganese, and was it possible to draw two samples of the same delivery of ferromanganese which did not differ more in composition than the various analyses enumerated differed among themselves?

Mr. SANITER, in reply, said that as far as he was aware there were no differences between his working and Mr. Pattinson's working of his process. The only difference is in the results obtained, the instructions given by Mr. Pattinson for the working of the process having been strictly followed out. He did not doubt Mr. Pattinson's results, which generally agreed with his own corrected result. He wished distinctly to state that, as shown in the table, some chemists had obtained 100 per cent. Mr. Pattinson had referred to a manganese ore which had been tested by himself and by Professor Fresenius. He had also an opportunity of testing that manganese ore, and he also agreed with Messrs. Pattinson and Fresenius within a few hundredths per cent., using the co-efficient obtained by testing some  $Mn_2O_4$  supplied by Mr. Pattinson, accepting his statement as to the amount of manganese which the  $Mn_2O_4$  contained, which he believed to be correct, simply because it confirmed his previous experience as given in Table II. He obtained only 99.35 per cent. of the manganese present in that  $Mn_2O_4$  prepared by Mr. Pattinson and used that co-efficient to calculate the ore just mentioned and then the result obtained read within a few hundredths per cent. of the results obtained by Fresenius and Mr. Pattinson. He quite recognised that Mr. Pattinson's results were 100 per cent.; at the same time he was not prepared to accept the opinion that the difference would be sure to be cleared up. The differences were of very long standing and had not yet been cleared up. His paper did not pretend to explain why those differences occurred, but to suggest the means of avoiding discrepancies in the ultimate analyses reported by chemists. Mr. Pattinson had also remarked that his method had been investigated by several distinguished chemists some considerable time since, amongst whom Professor Ledebur is mentioned. Now it was a fact, he believed, that in Germany Volhard's method was said to give 100 per cent. of the manganese present. Now if this were so his (Mr. Saniter's) results, being constantly different, should yet agree on the two methods. They did not. Volhard's

method gave higher results as compared with Mr. Pattinson's method. Mr. Pattinson also mentioned the difficulty in obtaining pure manganese compounds, but although it was difficult, he (Mr. Saniter) thought that any chemist, after he had obtained a fairly pure compound, should be able to analyse it for impurities, and thus arrive at the manganese it actually contained. Mr. Pattinson rather narrowed the point down to one between himself and the speaker, which was very far from his wish. His Table V. they would see showed that this was not the case. He sent his preparation to Mr. Stead, who obtained the theoretical result. Five other chemists obtained results considerably under 100 per cent. of the manganese present; it was those results they could not explain. The results were there, and all he wished was that chemists should check the method to be sure of the results they were obtaining. Mr. Gray had said that he obtained high results by the pyrophosphate method. That was quite possible, as lime or magnesia or baryta in solution must inevitably come down unless the manganese is first separated as sulphide. Personally he had tested against American chemists, and their results were not high, but low. Mr. Gray also pointed out that permanganate of potash was very undesirable as a reagent. There was great prejudice against permanganate of potash. He (Mr. Saniter) had used Volhard's method in testing manganese ores, and they had tested their permanganate solution months apart, and found it practically permanent when kept in the dark; he did not know whether it was so in the light. He was bound to say that for testing iron it was almost more delicate than bichromate, the pink colour being more definite than the green spot. He had stated in his paper that every precaution had been taken; he had used zinc chloride for the last three years. The burette was also carefully calibrated. It was not very difficult to arrive at the impurities. Dr. Kohn had asked if he had any direct evidence as to the volatilisation of manganese. In the experiment given he had estimated the amount of oxygen in excess of  $MnO$ , and found the whole deficiency was not due to the reduced quantity of oxygen in the precipitate. He had not tried the electrolytic method; it might be good, but he was afraid time was against them in commercial laboratories, whereas by Mr. Pattinson's method thoroughly accurate results could be turned out in a couple of hours. With regard to Dr. Hunter's question as to the value of the unit of manganese, he thought it was a good deal higher in ferromanganese than in manganese ores, but he had no figures at the moment. He did not think it was possible to draw two samples from a large cargo which would agree so closely as analyses on the same sample.

*Meeting held in the Victoria Hotel, on Friday,  
February 2nd, 1894.*

MR. IVAN LEVINSTEIN IN THE CHAIR.

The CHAIRMAN said that he desired to again call attention to a paper read by Mr. Carter Bell on the desirability of raising the flash point of mineral oils used for lighting purposes, for the reason of setting right some misapprehension that had taken hold of the minds of the Directors of the Ship Canal. The same subject had been considered at a subsequent meeting of the Chemical Section of the Manchester Chamber of Commerce, and reference was made to the probable danger that might arise to shipping and property belonging to the Ship Canal if large quantities of mineral oils of a low flash point were stored near the docks, and a resolution of the Section that it was desirable in the interests of public safety to raise the flash point to  $100^{\circ}$  was adopted by the Board of Directors of the Chamber. He was, however, very sorry to hear that the reference to the Ship Canal should have been misunderstood by the Directors of the canal, who were under the impression that the Section of the Chamber intended to agitate for only raising the flash point for oils arriving at the Manchester Docks. If that impression got into the heads of some people it would of course do considerable injury to the canal. With regard to the tolls and charges of the Ship Canal Company on chemicals, it had been suggested that a special sub-committee of our Section should be appointed to consider this question, but in his (the Chairman's) opinion, this was unnecessary, because this was already in the hands of the Chemical Section of the Chamber of Commerce, which was practically elected by them and represented the commercial interests of the chemical industries of the district. A full and exhaustive report on the subject had already been presented to the Chamber of Commerce and published in its monthly record, and they would find on reference to that report that the charges and tolls were in some instances heavier than the charges hitherto made, and this was principally due to the expense in carting to and from the docks. They had had an interview with Mr. Marshall Stevens, the manager of the canal, who went fully into their complaints, and if he did not succeed in overthrowing the report, he certainly enlightened them upon several points. There were reasons which he (the Chairman) was not prepared to state, that the freight from Liverpool to Manchester should not be reduced. In regard to the proposed meeting of merchants as to rates, sentiment would not bring business to the canal, but with equal rates he thought every loyal importer and exporter would support it.

SESSION 1893-94.

Friday, March 2nd:—

Mr. T. Clarkson, A.R.S.M. "A New Sampling Machine."  
Dr. F. H. Bowman, F.R.S.E. "Molecular Chemistry."

## NOTES ON THE "FERTILISERS AND FEEDING STUFFS ACT, 1893" (56 & 57 Vict. c. 56.), AND ON THE "FERTILISERS AND FEEDING STUFFS REGULATIONS, 1893."

BY J. CARTER BELL, A.R.S.M., ETC.

UNDER this Act, which came into force on the 1st January of this year, the farmer can bring a sample of manure or feeding stuff, together with the invoice of the goods, to a district analyst, and if the sample does not accord with the conditions of purchase as shown by the invoice, which has to state the percentages of soluble and insoluble phosphoric acid, nitrogen, and potash, if any present, then the seller is liable, under this new Act, to a penalty. All who have given any attention to the analyses of such substances as are covered by the Act, will be aware that various results may be obtained by different analysts, depending upon the methods of estimation. To illustrate this, I produce a circular issued by the Manchester Corporation some years since, in which it is stated "In consequence of damaging

statements having been circulated with reference to this manure ('made from human excrement, blood, bones, fish, &c.') the Health Committee have had samples drawn from stock by one of the professors of the Victoria University and by Mr. Carter Bell, and analysed by the under-mentioned chemists, with the following results<sup>1</sup>; then follows a table giving results obtained by seven analysts of repute—I abstract the salient points, analysts being represented by numbers:—

	Analysts.						
	1.	2.	3.	4.	5.	6.	7.
Organic matter*	29.68	36.14	33.03	29.24	31.53	38.52	35.54
Moisture.....	12.36	10.77	15.93	15.08	13.49	15.11	15.07
*N = ammonia.	2.81	2.99	2.82	2.61	2.50	2.84	2.73
Tribasic phosphate.....	3.66	6.39	4.32	4.72	4.80	4.60	5.16

No one can deny that the variations here are very great, and this time the usual excuse of bad sampling cannot be put forward, for the manure in the state of powder was well mixed in the laboratory and quickly put into bottles, corked and sealed in the presence of witnesses; in the estimation of the nitrogen we may say that the seven fairly agree, but in the other constituents the agreement is sadly wanting.

This Act is calculated to be of great benefit to the farmer and to the honest dealer. It is highly desirable that the effect should not be vitiated by conflicting analytical reports, hence I suggest that a committee, composed of manufacturers and analysts, be appointed at an early date, and the question of the analyses of manures and feeding stuffs be investigated by them. The question of sampling is an important one, but this is well covered by the "Regulations" issued by the Board of Agriculture. This society will be doing good work in suggesting that certain methods be employed for the estimation of the various constituents of the manures or feeding stuffs in question.

#### DISCUSSION.

Mr. T. TYRER said he was under the impression that in the matter referred to, sampling was regarded as of equal importance with analysis. He did not wish Mr. Bell to understand that he under-estimated the value of analysis. As a manufacturer he would prefer to have good sampling with an agreed method of analysis. There had never been any difficulty in determining what method should be adopted. The subject of manure analysis was brought before the London Chamber of Commerce and was thoroughly discussed by a committee and referred to the Manure Makers' Association, which had full powers. He believed he was correct in saying that the present Board of Agriculture had been in intimate connection with the Royal Agricultural Society of England, and they had assigned to Dr. Voelcker the duty of determining this question; therefore he could not see that any good result would be achieved by this Society taking the matter up again. The question of manure had become a matter for legislation, but he agreed from a manufacturer's point of view with having perfect methods of sampling. This difficulty of sampling had been pointed out by the Chairman, but dealers on one hand and sellers on the other often objected, inasmuch as the obtaining a fair sample was a matter of considerable difficulty. Wood pulp in hard masses certainly presented some difficulties. The decision almost unanimously arrived at by the Sections of the Society as to sampling had, in his opinion, equal force to-day.

It was proposed by Mr. Carter Bell that the Society form an analytical committee to investigate the various methods of analysing manures; this was seconded by Dr. Gerland, was put to the meeting, and carried *nem. con.*

#### NOTE ON THE ESTIMATION OF MOISTURE IN WOOD PULPS.

BY J. CARTER BELL, A.R.S.M., &c.

THE subject of Messrs. Readman's and Gemmell's paper before the Glasgow Section in December last, viz., The Estimation of Moisture in Wood Pulps, is of considerable interest and importance alike to the manufacturer and user as well as to the analyst to whom the estimation may be referred. With a view to a proper appreciation of the subject, and a satisfactory solution of the difficulties attending the analysis, I will first mention the method I adopt, and conclude with certain suggestions calculated to secure uniformity in the statement of results of analysis. I expose the sample to a temperature of 212° F., and so ascertain the absolute moisture present in the sample by difference. In stating my results, I allow a definite percentage of moisture. This I consider to be a much more scientific and satisfactory method than that of air-drying in a room at from 59° to 60° F., inasmuch as by the one process we arrive at a constant result, and by the second the result must be variable for many reasons; thus, the actual temperature of room, the varying amount of moisture in the atmosphere, the form and manner of exposure, i.e. in sheets or the layers separated, &c., &c. As an indication of this variation in results when air-dried, I give the following estimations taken from my note-book of wood pulp air-dried and also dried at 212° F.

October 1893. WOOD PULP exposed for 100 Hours to Temperature from 59° to 60° F.:—

Air-dried.		Dried at 212° F.	
	Per Cent.		Per Cent.
Moisture.....	59.3		69.3
	59.2		67.3
	59.4		67.0
	51.5		67.0
	55.8		66.5
	55.8		67.8
	61.8		65.5
Mean of 70 samples.)	58.4	Mean of 70 samples.)	66.77 moisture.
Air-dried pulp....)	41.6		
	100.0		

wood pulp, calculated to contain 10 per cent. of moisture would be 36.9 per cent. of air-dried pulp.

WOOD PULP, November 23rd, 1893, Air-dried for 60 Hours:—

	Per Cent.
100 grms. torn in pieces.....	Moisture 64
100 " " torn.....	63
50 " torn.....	65
100 " not torn.....	59
50 " ".....	61
50 " ".....	63

Mean of six samples "air-dried" for 60 hours... 62  
Percentage of moisture when dried at 212° F.... 66.6

In this case the manufacturer would be called upon to pay either for 37 tons or 38, whichever method had been used for estimating the moisture.

Three lots of 500 grms. each were weighed from the same sample. Nos. 1 and 2 were dried at 212° F., and the moisture was 56.1 and 56.4; these two dried lots were exposed in different rooms for 30 hours to temperatures

varying from 50° F. to 56° F.; the percentage of moisture was 52 in both cases, calculated on the original 500 grms.

The No. 3 500 grms. was exposed in a room for 24 hours to the same temperature as the above; the percentage of moisture was 48·2, or 51·8 of air-dried pulp.

According to experiments Nos. 1 and 2, the paper manufacturer would be called upon to pay for 48·6 tons of air-dried pulp containing 10 per cent. of water, but according to No. 3 it would be 51·8 tons.

One authority suggests that in estimating the moisture we first ascertain the absolute amount by drying at 212° F. and then allow 8 per cent.; others suggest 10 per cent., and a third 12 per cent. I repeat with emphasis that in my opinion we must adopt the method of estimation at 212° F., with subsequent allowance of a definite and agreed percentage of moisture. My suggestion is that this subject is of sufficient importance to justify the appointment of a "joint committee" composed of equal numbers of wood-pulp manufacturers or dealers, of paper manufacturers, and of analysts, all of recognised status, so as to ensure that the recommendations of such joint committee shall be regarded henceforth as the basis of contract. Let a committee so composed, through the agency of this Society, thoroughly investigate the whole subject and so secure for buyer and seller alike equal justice, and remove the onus from the analyst of stating results obtained by a method of estimation varying from that adopted by the opposing analyst.

## NOTES ON THE OXIDATION AND CORROSION OF IRON AND STEEL.

BY WILLIAM THOMSON, F.R.S.E.

I HAVE lately been experimenting to find the best protective coating for iron and steel work with special reference to structures which are situated in the neighbourhood of the sea, and exposed to the spray of the salt water. It required a number of experiments before a satisfactory method was obtained for making the tests. In comparing a number of different paints the thickness or weight of the coating must be considered as these vary to a large extent.

I obtained pieces of steel  $4 \times 1\frac{3}{4} \times \frac{1}{8}$  ins. drilled each with a hole in the top, these were weighed and painted with one coating of each of the paints and weighed again, then left for about a week exposed to the atmosphere, and again weighed, the difference between the two first weights gave the weight of the wet paint employed which was calculated for the square yard of surface whilst the first deducted from the third weight gave the weight of dry paint. The coatings varied between three quarters of an ounce for boiled linseed oil alone, to seven ounces for oxide of iron paint, tar 1·56, solution of pitch 1·24, red lead 6·24, &c.

These pieces of painted steel were then suspended and sprayed from time to time with a saline solution composed of a mixture of the chlorides of sodium and magnesium in about the proportions in which they would be found in sea-water, but this showed no satisfactory result, as there was no appearances shown on any of the samples to indicate rusting underneath the covering. I then immersed all the plates in a glass vessel containing sufficient saline solution to half immerse each and observed that the clear solution

\* In this test, pieces of the wire 6 inches in length were twisted till they broke, and the number of twists required are here recorded.

after two or three days gradually began to become turbid, and in a few days more threw down a precipitate of the peroxide of iron. Some time later it could be observed that the iron underneath some of the coatings of paint was undergoing oxidation to a much greater extent than under others. It suggested itself to me that if each plate of iron were placed in a separate glass beaker with the saline solution the turbidity of the clear liquid would be some criterion as to the extent of the rusting underneath.

On making a second series of experiments in this way I observed that the production of a turbidity formed a very good criterion as to the protective power of certain paints, and it has enabled me to make a large number of experiments with different coatings which showed that oxide of iron paint, white lead, and the ordinary paints of commerce had comparatively little protective influence on the iron as compared with red lead, the latter showed no signs of turbidity in the saline solution whilst all the others had become turbid and deposited a considerable precipitate of ferric oxide.

The study of this subject was subsequently carried on in conjunction with Mr. Harry Smith, F.I.C., which has resulted in the discovery of some valuable applications for the prevention of corrosion, but as he has applied for a patent to cover his special claims I will leave him to describe these further experiments himself.

I took two small pieces of iron, attached them by copper wires, the one to a plate of copper of small size, and the other to a plate of zinc, these being allowed to stand in the saline solution. It was remarkable to observe how rapidly the iron in contact with the copper became corroded and how completely the iron in contact with the zinc was preserved from corrosion or oxidation, not only on the part in the solution itself but also on that which was not immersed. After a few weeks an electro deposit of zinc was formed on the immersed portion of the iron plate in contact with the zinc.

It suggested itself to me as probable that for the protection of bridges and towers it might be advisable to place a large ball of zinc in wet ground in metallic contact with the iron of the structure by means of wires which I believe would tend materially to prevent corrosion at comparatively small cost.

I have lately been considering the effects of riveting iron and steel on the one hand, and different kinds of steel on the other, in the manufacture of iron and steel boilers with a view to find whether the contact of these different materials would tend to cause corrosion in the one or in the other, by reason of the one acting as electro negative to the other and so inducing electric action resulting in oxidation and corrosion of one of the plates.

I lately came across a peculiar effect produced on the bowling hoop of a steel boiler which had been attached by iron rivets, the bowling hoop being deeply corroded at certain points, especially in the line along the outside ridge. I had cut from the steel bowling hoop a piece of steel  $\frac{1}{2}$  in. square by  $\frac{1}{8}$  in. long, and from one of the iron rivets I had a piece of similar size also cut; a hole was drilled through each near the top into which a copper wire was fixed; for comparison with these pieces I also obtained similar pieces in size and shape which I marked "C," this was a new steel rivet; "D" was a steel rivet closed by machine and held in the dies till nearly cold; "E" was a piece of new mild steel (unworked).

The piece of iron taken from the rivet in the boiler above mentioned was Low Moor iron which I marked "A," the piece cut from the steel bowling hoop I marked "B." The whole of these samples were pushed through a piece of cardboard, so that all could be immersed in any liquid at the same time. By merely touching the copper wires attached to each with the wires leading from a Thomson's tangent galvanometer, the direction, and to some extent the intensity, of the current of electricity produced (if any) could be ascertained by noticing to which side the spot of light was deflected and the rapidity with which the deflection took place. On looking at the annexed table it will be seen that "A," the piece from the iron rivet, and "B," the piece from the steel hoop when placed in sulphuric acid, and connected to the galvanometer the rivet was electro positive to the

steel at first and thus acted the part of the zinc or more easily corroded material, but within a few seconds afterwards the spot of light swung round in the opposite direction, showing that the iron rivet had become electro negative to the steel. The piece of iron rivet was then placed in contact with the piece from the new steel rivet "C," and the same effect took place, the iron rivet being electro-positive at first and electro-negative afterwards. Exactly the same thing took place when the iron rivet was placed in contact with the second steel rivet, closed by machine "D," but when placed in contact with a piece of "mild steel new unworked" "E," the iron remained from the first electro negative, the mild steel being electro positive.

The general results, as shown by the table given below, are that the three samples of steel "C," "D," and "E," all react strongly amongst themselves, and therefore it seems to be quite as likely that one steel plate may act as electro negative to another steel plate, as it is for a piece of malleable iron to act as electro-negative to a steel plate, although it may be taken as a rule that steel corrodes more readily than iron when placed under favourable conditions.

Combinations,	Sulphuric Acid (And 1 part to Water 9 parts).	Caustic Potash Solution. Sp. gr. 1.311.	Chloride of Ammonium Solution. Sp. gr. 1.033.
A & B	+ A at first, + B afterwards.	+ B at first, the current rapidly going down to zero.	+ A very strongly on continued action, + B very weak, almost nil.
A & C	+ A at first, + C afterwards.	+ C very strongly	+ A very strongly, afterwards the current decreased to zero, but no reversal.
A & D	+ A at first, + D afterwards.	+ D " "	+ A at first weakly, afterwards + D weakly.
A & E	+ E	+ E " "	+ A strongly at first, gradually becoming very weak, but showed no reversal.
B & C	+ C	+ C at first fairly strongly, then + B fairly strongly.	+ C strong at first, afterwards very weak.
B & D	+ B slightly, + D afterwards.	+ B at first fairly strong, then reversing to + D, reversing again to + B rather strongly.	+ B strong at first, afterwards + D weakly.
B & E	+ B momentarily, then + E afterwards.	+ B momentarily, then + E very weakly.	+ B strong at first, afterwards weak, but no reversal.
C & D	+ C momentarily, then + D afterwards.	+ C very strongly	+ C " "
C & E	+ C strongly at first, afterwards becoming extremely weak. Sometimes on one side and sometimes on the other.	+ E fairly strongly.	+ E " "
D & E		+ E very strongly	+ D " "

Copper with all the samples was "+" (electro-positive) in caustic potash solution, and "-" (electro-negative) in sulphuric acid and chloride of ammonium solutions.

The + sign corresponds to the electro-positive, i.e., the zinc element which becomes corroded, whilst the sign - corresponds to the copper element which does not corrode.

Much interesting work in this direction has been made by Mr. Thomas Andrews, Asso. M.I.C.E., F.C.S., &c.\* He shows that in some combinations of steel of different

\* On "the Relative Electro-Chemical Positions of Wrought Iron, Steels, Cast Metal, &c. in Sea-Water and other Solutions." Read before the Royal Society of Edinburgh, and also one by the same author on "Galvanic Action between Wrought Iron, Cast Metals, and various Steels during Long Exposure in Sea-Water." Read before the Institution of Civil Engineers, Vol. LXXXVII, Session 1883-84, Part III., and a third by the same author, on "Corrosion of Metals during Long Exposure in Sea-Water." Proceedings of the Institution of Civil Engineers, Vol. LXXXII, Session 1884-85, Part IV.

kinds with each other and with iron that the one element after being electro-positive gradually becomes electro-negative, and this change will take place many times during long contact with each other. In other cases the relative galvanic positions of the two pieces of metal remaining constantly the same. Under such conditions it seems an advisable thing that in making boilers some use should be made of this simple means of determining whether the one metal intended for use in the boiler would be likely to act strongly upon another when both are placed in galvanic contact with each other in a saline solution.

I have lately been investigating a curious case, in which a number of steel boilers were completely destroyed by using them for producing steam, and at the same time for evaporating solutions of caustic soda from 5 to 12 per cent. The result of the use of the boilers in this manner was, in about two years, to crack many of the plates along the line of the rivets, but not between the rivet holes, and in many cases the rivet heads were broken off. I was informed that this was one of the peculiar properties of caustic soda upon iron or steel, that "it took the nature out of the steel, and caused them to become brittle."

I made a number of experiments to find whether caustic soda had any effect whatever upon iron and steel, by taking—

A. Four pieces of puddled iron and four pieces of steel wire, and placing them in a five per cent. solution of caustic soda (made from ammonia soda ash) contained in iron tubes closed by a screw cap.

B. Four pieces of each as above, placed in a 12 per cent. solution of caustic soda as above described.

C. Two pieces of each wire placed in distilled water in an iron tube similarly arranged.

D. Four pieces of hoop steel placed in 5 and 12 per cent. solutions respectively of caustic soda as above mentioned.

In all these experiments one set of each was kept at the boiling point of water constantly for 84 days, and the other set kept in the cold, the whole being immersed for 195 days (about 6½ months).

The breaking strains of the pieces of wire in samples untreated in comparison with those which were thus treated were kindly determined for me by Mr. John Thewlis Johnson of Manchester, and the breaking strains of the hoop-steel by Mr. Alderman W. H. Bailey of Salford.

The results as a whole show that caustic soda appears either hot or cold, to have little or no chemical or damaging action on the iron, which is what one would have expected. I had in my possession till lately some pieces of bright iron which had been put by my late partner, Dr. F. Crace-Calvert, in a solution of carbonate of soda and left for upwards of 30 years, and they were as bright at the end of that period as they were when first immersed. I am of opinion that the damage to the steel boilers is a purely mechanical one, caused possibly by the caustic getting under the rivet heads and between the plates, crystallising and thus breaking them by expansion underneath.

#### DISCUSSION.

The CHAIRMAN wished to know what in the opinion of the author of the paper was the best paint to be used for the protection of iron?

Mr. THOMSON replied that red lead was usually employed by the Admiralty for painting iron ships, and might be considered the best, notwithstanding that it very often caused poisoning to the men engaged in cleaning the interior of ships.

Mr. PETER HART.—Some boilers used for boiling caustic soda solutions only gave way near the furnaces, and the bolt heads broke off. This showed that it was purely a mechanical action, and not the result of corrosion from the action of caustic soda.

## SUBSTANTIVE DYES AND SUBSTANTIVE DYEING. A CONTRIBUTION TO THE THEORY OF DYEING.

BY CARL OTTO WEBER, PH.D., F.C.S.

THE theory of dyeing has so far scarcely exercised any direct influence upon the art of dyeing, none of the exceedingly numerous methods for dyeing and printing having been evolved from a theory of dyeing in a similar manner, as, for instance, the manufacture of triphenylmethane colouring matters from the well-known series of theoretical researches on their constitution. At present two essentially different theories of dyeing are opposing each other, one of which considers dyeing as a chemical process, while the other regards it as a merely physical phenomenon. Witt's "solution theory" is no doubt the most notable representative of the last named class. It appears that the adherents of these theories never seriously attempted a rational compromise between their divergent opinions, one always striving to prove the other unsatisfactory or untenable. This of course might be justified if proof had ever been furnished that the whole of the dyeing phenomena, as observed in the dyeing of the various fibres with dyes of different classes, belong to one order of chemical or physical phenomena only. But indeed we know that the behaviour of each of the different fibres towards the same dye shows great differences, and so does the behaviour of one and the same fibre towards dyes of the various classes indicate very considerable variations. That there exists an undeniable connection between these differences and the chemical nature of these textile materials and dyes is an old observation. Especially well established is the fact that a coloured substance, in order to be applicable as a textile dye, must of necessity possess the properties and constitution of either an acid or a base.\* Thus, indigo

\* This definition of course does not and is not meant to cover also the pigment dyes, amongst which not only the well-known dye pigments, but also aniline black and indigo must be classed.

cannot be called a dye, but should be described as a pigment colour, while on the other hand indigo-caruine is a true dye. There exists no exception to the above rule, which certainly seems to confirm the chemical theory of dyeing. But we are forced to the conclusion that the dyeing processes must be divided into at least two different classes, according to whether the dyes are directly assimilated by the fibre (substantive dyeing), or whether they require the intervention of a mordant, or are formed immediately in and upon the fibre (adjective dyeing). The first case forms the subject of this investigation, together with the relations between the chemical nature of fibre and dye, upon which substantive dyeing depends. The second case (adjective dyeing) will not occupy our time here. Dyeing in this case is a process practically independent of the fibre,\* in so far as the latter assumes no chemical rôle in the fixing or formation of the dye or pigment, but merely acts as a carrier for the latter. These dyes therefore either mechanically adhere to the fibre, or they occur in the cellular cavities of the latter in the form of insoluble precipitates. For this reason, all dyes of this class are very liable to show the defect known as "rubbing off," and indeed they are never without it. Indigo, aniline black, Turkey red, and all mordant dyes on cotton, also the azo dyes produced upon the fibre are pigment dyes of this class, just like chrome yellow, Prussian blue, or iron buff. There are scarcely two opinions possible with regard to this kind of dyeing and dyes.

Of the various textile fibres, wool has no doubt the greatest affinity to colouring matters of all kinds, and is capable of decomposing the basic dyes into free acid and colour-base which combines with the wool, also of combining directly with the colour acids of sulphonated dyes. In all these cases the wool is dyed in shades identical with those of the salts, or rather the lakes of these dyes. This property of wool to combine with colour-bases as well as with colour acids, has received its full explanation by the valuable investigations of Knecht,† who most conclusively demonstrated this function to be due to the amido-acid nature of the wool-fibre, particularly to lanugine acid. It is a matter of little importance for the discussion of this subject, whether the wool fibre is a homogeneous substance or not, or whether lanugine acid pre-exists on the fibre or is a decomposition product of the latter, which forms in the course of the dyeing process. The fact that wool is capable of forming lakes with colour bases and colour acids in the manner of an amido acid is well established and we can therefore express the chemical nature of the wool fibre by the formula—

in which W stands for an unknown radicle, which may or may not be homogeneous in itself and which to us is of no concern beyond being the carrier of an amido group and a carboxyl group, i.e., of basic and acid properties respectively. Therefore while this formula only in the widest sense of the term could be called an empirical formula, it contains on the other hand no hypothetical assumption, the presence of amido and carboxyl groups in the wool fibre being a matter beyond dispute. This elementary formula being granted, wool dyed with naphthol orange would then be—

and likewise wool dyed with magenta.

\* Except in the case of the sulphonated or carboxylated, and mordant-dyeing wool dyes, which occupy a very interesting intermediate position between substantive and adjective dyes.

† These investigations have evidently been suggested by certain remarks of Prof. Hummel (Journ. Soc. Dyers and Col., Vol. 1, pp. 208–210), who appears to have clearly recognised the nature of the process of dyeing wool long before Knecht undertook his researches.

The process of the assimilation of these and all analogous colouring matters by the wool fibre is a purely chemical reaction, which is in itself sufficiently intelligible without Witt's theory of rigid solutions. What takes place in these dyeing processes is simply the formation of lakes between the amido or the sulphonic group of the wool and the respectively antagonistic sulphone or amido group of the acid or basic colouring matters. The second of our above formulae expresses the fact, that in dyeing wool with a sulphonated colouring matter, the amido group of the wool combines with the sulphonic group of the dye, while the carboxyl group of the wool remains unaffected. The third of our formulae represents the process of dyeing wool with magenta as lake formation between the carboxyl group of the wool, and one of the amido groups of magenta. Consequently we should expect that the free carboxyl group of wool dyed with some acid colouring matter, would still be capable of combining with basic dyes in the same manner and degree as undyed wool. Such indeed is the case. A skein of wool dyed in the presence of a large excess of scarlet R was carefully washed after dyeing. On immersion of this skein in a bath of magenta, side by side with a white skein of the same weight, which was treated in a magenta bath of the same strength, it was found that both skeins assimilated exactly the same quantity of magenta. Considering, however, that the solutions of all acid colouring matters precipitate the solutions of all basic colouring matters, lakes being formed, which must be described as salts of colour bases with colour acids, it might be suggested that the magenta in the above dyeing test did not combine with the carboxyl group of the wool, but formed a lake with the acid dye upon the fibre, in which case the wool would simply be dyed with a kind of pigment, a magenta-scarlet lake. But lakes of this description are, without exception, easily soluble in alcohol. However, in treating with alcohol the hank dyed with scarlet and magenta, only a very small quantity of magenta, but not the faintest trace of scarlet is dissolved. This is an undisputable proof that upon such skein scarlet and magenta occur quite independently of each other; in other words, wool dyed in this manner is a compound lake of the formula—

The disciples of the "solution hypothesis" might observe that the negative result of the alcohol test was not the necessary result of a chemical combination of the above description, but simply the consequence of the greater solubility of those dyes in the substance of the wool fibre than in alcohol, for this hypothesis certainly has the advantage of offering a cut and dried answer for every emergency of this kind. Now, assuming for the nonce this hypothesis to be right, then we should have dissolved in the wool fibre magenta side by side with scarlet, so that just in this case under all circumstances the above-mentioned magenta-scarlet would of necessity be formed, but this is exactly what is disproved by the negative alcohol test. Witt's hypothesis is very difficult to refute, because it is almost uncontrollable, and if we attempt to disprove it, we must bear in mind that it assumes the colouring matters to be in a state of solution in the fibre, i.e., in the free state. As soon as any chemical action between fibre and dye is allowed, the hypothesis becomes altogether superfluous. I shall show later on that we possess the means for the experimental determination of this matter.

The second objection raised against the chemical theory of dyeing contends that no chemical combination between the wool fibre and the dyes did take place in dyeing, as the

of very much the same order as the formation of a salt from acid and base. Witt's solution theory applied to substantive wool dyeing becomes involved at every step in insuperable difficulties.

Especially interesting are the phenomena of substantive dyeing on cotton. This fibre, or rather cellulose, is a very indifferent substance as compared with wool or silk. This indifference is even more pronounced in its behaviour to dyestuffs, as compared with substances producing deeper chemical changes. The aldehydic nature of cellulose, and the absence in it of lake-forming acid or basic groups, goes a long way towards the explanation of this indifference. As soon as we fix upon the cotton a carboxyl group (tannic acid) or an amido group (by Vignon's process), the fibre behaves to basic and acid dyes respectively, like wool. On the other hand, it is well known that without such a preparation, cotton is capable of assimilating direct many basic dyes and also the numerous so-called benzidine dyes. This is particularly surprising with regard to the last named class of dyestuffs, which, from a chemical point of view, are of the same type as the familiar wool scarlets and croceines, which altogether lack the capability of dyeing cotton direct, while most of the benzidine dyes are also wool dyes of high excellence.

But substantive dyeing on cotton, even with the basic dyes, appears very puzzling, there being no lake-forming group whatever in cotton. It is true that our knowledge of the chemical constitution of cotton is very deficient as yet; but still we know for certain that any salt-forming energy the hydroxyl groups of cellulose might possess, is very small, as is readily inferred from the fact that no free acid is ever observed in dye baths of basic dyes even when they are completely exhausted by the cotton.\* This observation therefore goes to prove that cotton, unlike wool, which only takes up the free colour-bases, assimilates the complete colour salts. But, nevertheless, it will have to be taken into consideration that oxycellulose shows a very considerably increased affinity for basic dyes, so that strongly chemicked cotton dyes much darker shades with these dyes than merely soured cotton, and this gains additional significance by the fact that oxycellulose is of a much more pronounced acid nature than ordinary cellulose. But in dyeing oxycellulose with basic colours we again fail to discover free acid in the dye baths, and it appears therefore as if the phenomenon of substantive dyeing on cotton with basic colours could not be understood as a chemical process, and would therefore justify the introduction into the theory of dyeing of a new principle, such as Witt's solution hypothesis.

Adjective dyeing (mordant dyeing) is admitted by every one to be a purely chemical process, that substantive wool dyeing is accomplished by virtue of chemical processes of an identical order (lake formation) has been proved above. On the other hand we shall see presently that from cogent chemical reasons we must in other cases admit the existence of the dye in the fibre in a state of solution. It is only to be expected that occasionally two of these processes concur in producing the dyeing result. In this case the dyeing operation is really a very complex process, an example of which may prove of interest.

The dyeing of alizarin upon chromed wool is a typical case of adjective dyeing. The dyeing of diamine fast red upon wool in an acid bath is an equally typical case of substantive wool dyeing, consisting, according to what I have shown above, in the formation of a lake between the amido group of the wool and the sulphonic group of the dye.

\* In relation to this a recent observation by Knecht (Journ. Soc. Dyers and Col. 1893, 114) is of interest. He noticed that in placing a drop of a solution of magenta upon bibulous paper, it expands rapidly into a circular stain, and subsequently a halo of apparently pure water forms round this stain, and this water is of a distinctly acid reaction. Evidently a dissociation of the magenta into hydrochloric acid, and a basic salt of magenta has taken place. Whether this dissociation is caused by the difference in the ratio of diffusion of the components of magenta, or has to be considered as the action of the weak acid cellulose of the paper cannot be decided yet; but it is worth pointing out that this observation stands on a par with the phenomena accompanying the formation of dissociation le's (this Journ. 1891, 398) from basic dyes and china clay.

Kertesz showed that by treating wool thus dyed with chromium fluoride, the fastness of the dye is increased in a most remarkable degree. This action of chromium fluoride is due to the formation of a chromium lake in the oxy-carboxyl group—

of the dye, which, in this respect, behaves exactly like the ortho-dihydroxyl group of the alizarin dyes. Dyes not containing one of these two lake-forming groups are quite indifferent to chromium fluoride, and this is the reason why the practical results obtained with this chromium salt led to such a difference of opinion as to its value. When indiscriminately applied to a number of wool dyes selected at random, the results obtained with this salt are sure to prove confusing, if not discouraging. But whenever a wool-dye contains besides the sulpho group, either of the two above-mentioned lake-forming groups, subsequent treatment with chromium fluoride is certain to act beneficially. Our above example therefore indicates a dual dyeing process which is at the same time both a substantive and an adjective dyeing process. Similar combinations can occur between adjective dyeing and substantive dyeing respectively, and solution. It is scarcely necessary to point out that combinations between substantive dyeing and dyeing by solution, are only possible in such cases where the chemical energy of the fibre, which is the primary condition of substantive dyeing, is extremely weak. This, however, is exactly what we observe in the case of cotton being the material to be dyed. This fibre is necessarily devoid of basic properties, and its acid properties are of the weakest description. The temptation under these conditions is, no doubt, very great to look upon this indifferent behaviour of the cotton fibre as *prima facie* evidence for Witt's solution theory. Nevertheless, I am of opinion that substantive dyeing upon cotton with basic dyes can be satisfactorily explained as a chemical process of a similar kind as the process of substantive wool dyeing.

The fact that, as above stated, cotton does not fix the base only of the basic dyes, but takes up the whole of the colour salt, appears strongly in favour of Witt's hypothesis, and this important fact that cotton, substantively dyed with basic dyes, contains the latter still in combination with their respective acids can easily be demonstrated.

Rawson\* showed some years ago that the strength of naphthol yellow can be most accurately determined by titration with Night blue. This means, in other words, that between definite proportions of these two dyes a chemical reaction takes place, and this reaction is simply lake-formation between the Naphthol-yellow acid and the Night blue base, the lake formed being—

\* Journ. Soc. Dyers and Col. 1888, 82.

On the other hand, naphthol yellow does not decompose an already formed night blue lake, just as barium chloride is incapable of forming a lake with naphthol-scarlet dyed on wool. This loss of reactive energy of both the basic and acid constituents of lakes is a very remarkable fact. In some cases it goes so far that the lake-forming metallic oxide can no longer be detected in these lakes by means of the ordinary reagents. The behaviour of the alumina in alumina alizarate and of the iron in naphthol green are typical instances of this kind.

Now, if we dye a skein of cotton with night blue, wash it, and pass it then through a solution of naphthol yellow S, the skein at once assumes a dark green colour and the dye is remarkably fast. If we repeat this experiment with a skein of cotton mordanted with tannic acid, we find that in this case the treatment with naphthol yellow produces no alteration. It is evident therefore that in the first case the dye, without any chemical change, migrate from the dye-bath into the cotton fibre, and all the reactions the aqueous solution of this dye is capable of, are consequently also obtainable with the dye on the cotton fibre. The tannin-mordanted skein, however, contains the night blue in the form of its tannin lake, and this accounts sufficiently for its indifference towards naphthol yellow. This leaves no doubt that whatever is the cause of night blue, like many other basic dyestuffs, dyeing cotton substantively, no lake formation can have occurred in the salt-forming amido group of the dye.

These facts with regard to substantive dyeing with basic dyes present all the requisite appearances for the consideration of this dyeing process as a solution phenomenon in the sense of Witt's hypothesis. But however weighty in this respect the above stated facts might appear, they are after all only a one-sided view of the subject, in so far as we have only taken notice of the behaviour of the dyes in this substantive dyeing process, without considering the behavior of the cotton fibre. The latter, although being a very indifferent chemical substance, is proved, through the recent observations of Cross, Bevan, and Beadle\* to be a rather stronger acid than it was generally supposed to be. But apart from this observation the capability of cotton to form saltlike compounds with the alkalis and several metallic oxides, especially plumbic oxide, is a well established fact. In dyeing scoured cops with basic dyes and cutting them in sections at various stages of the dyeing operation, we find that the strength of the dye is not decreasing from the outside of the cops towards the centre, as should be the case if the dyeing was due to a solution of the dye in the fibre. On the contrary we find the half-dyed cops to consist of a perfectly white centre surrounded by a sharply defined annular zone, which is quite evenly dyed. Exactly the same is observed in the dyeing of tannin mordanted cops. We know that this must be due to the definite capacity of combination tannic acid has for every basic dye, but at the same time we must necessarily assume the existence of similar relations between the cotton fibre or substance and the basic dyes. In this manner only can we explain the progressing by leaps of the dyed zone in the cops, instead of the gradual decrease of the depth of shade from the outside to the inside of the cops. We shall now have to enquire into the cause of this phenomenon.

Some time ago I showed that all normal tannin lakes are di-acid salts of the colour bases, and this fact seems to me to contain the solution of the above problem. The acid nature of the cotton substance is indisputable, but it is too feeble to abstract, like wool, from the basic dyes the colourbase with liberation of the acid. It is, however, quite strong enough to fix the whole of the basic colour salt, forming with it a di-acid lake by combining with one of the free amido-groups of the dye. It can be readily inferred that such a lake must be very unstable, especially against alkalis, and indeed we find generally that substantive basic dyes on cotton are very sensitive to soap.\* This view of the nature of the substantive dyeing process of cotton is thoroughly confirmed by the much increased affinity to

basic dyes shown by oxycellulose, an increase which, while being a necessary consequence if lake formation is the fundamental principle of this case of substantive dyeing, is utterly unaccountable from the point of view of Witt's solution theory.

Entirely different are the circumstances in regard to direct dyeing with the so-called benzidine dyes. According to their constitution these dyes must be counted amongst the acid dyestuffs. Indeed, most of the benzidine dyes are much better wool dyes than cotton dyes. The quite unexpected property of these colouring matters to dye cotton direct in either a neutral or alkaline bath, naturally called forth various attempts towards the explanation of the surprising fact. Mohlau\* thought to explain it from his observation that cotton could be "mordanted" with benzidine-chloride, and by subsequently diazotising this mordant and developing it in naphthionate, congo red was produced upon the fibre. From this he thinks himself justified to conclude that it is the paradiamido-diphenyl group of the benzidine dyes which is the cause of their seeming affinity to cotton. If such an affinity really exists, which by the way I absolutely deny, it can only be intelligible if it consists in the affinity of the amido groups of diamido-diphenyl to the weakly acid cellulose molecule. But in converting diamidodiphenyl into benzidine dyes, these amido groups are transformed into diazo groups, and their basic properties become absolutely extinct the same moment the actual dyestuff is formed. Consequently the cause of the alleged affinity between diamidodiphenyl and cotton, cannot by any means be the cause of the affinity existing between benzidine dyes and cotton. Even if we are prepared to concede the existence of some occult attraction intervening between the diphenyl residue and cotton, we only gain a very questionable advantage, explaining the mysterious affinity of the diphenyl dyes to the cotton fibre by the equally mysterious affinity of the diphenyl group. The discovery of numerous direct dyes containing no diphenyl group, deprived this so-called explanation of its last support.

Schultz thought the desired explanation might be found in the fact that the solutions of the benzidine dyes really are exceedingly fine suspensions only, which on prolonged standing deposit practically the whole of the apparently dissolved colouring matters. Schultz therefore evidently considers the dyeing of cotton with the benzidine dyes a mechanical process of the same order as the bleaching of textile fabrics with ultramarine blue suspended in water. It certainly cannot be denied that amongst the benzidine dyes a remarkably great number of difficultly soluble products occurs, but on the other hand there is at present no scarcity of very readily soluble dyes of this class. Moreover, the fastness of the benzidine dyes against rubbing is infinitely greater, as a dyeing process of the kind proposed by Schultz would yield. This author's explanation is further scarcely compatible with the fact that all these dyes are applied in boiling dye-baths, while for a dyeing process of that kind cold baths should answer quite as well. It is therefore evident that Schultz's explanation is contrary to the most essential facts concerning the application of these dyes.

That, however, cotton dyed with benzidine dyes contains the dye in its original form, i.e., as a colour salt, is evident from the fact that the sensitiveness of these dyes against acids is exactly the same, whether we have the dye fixed upon or in the cotton fibre, or whether we have it in aqueous solution. Remembering further that cotton is always dyed in alkaline solutions of these dyes, it is also clear that no decomposition of the colour salt into free dye-acid and alkali can take place, for the simple reason that cotton does not possess, like wool, amido groups capable of combining with free dye-acids with formation of a lake. But indeed it can be proved beyond doubt that benzidine dyes dyed on cotton exist in the latter in an absolutely unaltered condition. If we treat a skein of cotton dyed with one of these dyes in the solution of a barium salt, the colouring matter contained in the fibre is at once converted

\* Certain basic dyes, however, as, for instance, indazine (Casella), dyed on cotton without a mordant, seem, contrary to the above statement, to stand soaping perfectly well. But this is in every case due to the more or less complete insolubility of the free bases and oleates of these dyes in aqueous soap solutions.

\* Ber. 1888, 2014.

into a barium lake. Numerous inorganic salts can be used with the same result in place of barium chloride. Thus we see that these colouring matters in becoming fixed upon the fibre do not lose their characteristic lake-forming properties, and this fact implies that the assimilation of these dyes by the cotton fibre is certainly not due to some process of lake-formation, as in this case subsequent treatment with barium-chloride could have no effect. Still more striking is the behaviour of cotton dyed with these direct colours against solutions of the basic dyes, the latter being fixed by the former exactly as if the cotton had been mordanted with tannic acid. This fact, which was first observed by Messrs. Bayer and Co., of Elberfeld, who considered it a specific property of the benzidine dyes, has never been properly understood, and was the cause of a great confusion of ideas, which finds characteristic expression in the following passage from Schultz's *Chemistry of the coal-tar colours* (II. German edition, Vol. II., 341). This author says that, "the affinity of the benzidine dyes to the cotton fibre is so great that dyes of this group behave upon the cotton like mordants so that basic dyes can be dyed upon such cotton without previously mordanting it." It is difficult to see what the capability of the benzidine dyes to form lakes with the basic dyes has to do with the supposed affinity of the former to the cotton fibre. We might as well say that the affinity of tannic acid to the cotton fibre goes so far that cotton mordanted with tannic acid can be dyed with the basic dyes. As a matter of fact the capability of the benzidine dyes to form lakes with metallic salts or basic dyes is in no way connected with their property to dye cotton direct, but is merely a function of the dye-acid contained in these dyes, which by virtue of its acid nature acts exactly like tannin, the specific function of which is also purely that of an acid forming insoluble salts with the basic dyes. Moreover, that behaviour of the benzidine dyes is by no means characteristic of them. Any acid dye, no matter whether it be applicable to cotton or not, will show the same capability to form lakes with the basic dyes, as long as there are any free sulpho groups, or sulpho groups in combination with alkali only. A case of this kind we have already met with in the night blue-naphthol yellow lake. The behaviour of cotton dyed with benzidine dyes therefore only proves that these dyes exist in the fibre in the free state; in other words, as in a solution. Lake-formation between cotton and benzidine dye is out of the question, and this also explains the rather low average of fastness to light which these dyes show on cotton, while many of them on wool produce shades of an extraordinary degree of fastness, not only to light, but also to milling. It is an unquestionable fact that the fastness of a dye shows considerable variations according to the method of its application, and we find invariably that the fastest shades are obtained by that method which best provides for the specific lake-forming tendencies of every dye. Diamine fast red on cotton is very unsatisfactory, the dye having no chance whatever to form a lake. Dyed on wool in the manner of an acid dye, lake-formation in the sulpho-group takes place, and we obtain a shade of very considerable fastness. By subsequently treating the dye with chromium fluoride, a chromium-lake is formed in the residual group

of the dye, and the result is a shade of almost unexampled fastness.

In the above we have, by means of chemical reasons, established the fact that the benzidine dyes exist in the cotton fibre in the form of their original colour salts, and not in the form of lakes. For this reason these dyes react upon the fibre with all those substances, and in exactly the same manner as their solutions in water. The next question is therefore as to the manner in which these dyes are fixed by the cotton fibre. It might appear now as if an answer to this question might readily be found in Witt's solution hypothesis, this hypothesis being in perfect accord with the above discussed facts. On the other hand, however, we

must not forget that Witt's hypothesis goes beyond the mere adoption of the physical principle of solution for the explanation of the dyeing process in question, but makes the further assumption that the solvent in this dyeing process by solution is the substance of the cotton fibre, cellulose, itself. And this is the point where I hold that Witt's solution hypothesis is vulnerable. This hypothesis is an ingenious analogy, but, like all analogies, it also is an incentive to superficiality, and its uncontrollable elasticity renders it almost unfit for scientific purposes.

All benzidine dyes are applied in dye baths containing besides the colouring matter always certain indifferent salts, generally also alkalis and soap. The presence of these salts reduces the solubility of the dye, or, as we may put it, imparts to the dye bath the properties of a more concentrated solution of the dye, as is expressed by the ratio of dye and water present. A higher concentration of the dye bath, however, is tantamount to a higher osmotic pressure of the dissolved dye and the well known practical advantages of the addition of these salts, only confirm therefore the above conclusion, deduced from chemical facts that the dyeing of cotton with these dyes undoubtedly is a solution phenomenon. This leaves only the question after the solvent, into which the dye diffuses, to be decided. Witt of course declares that osmotic migration of the dye into the cellulose itself takes place, with formation of what Knecht first termed a "rigid solution." This I most decidedly dispute, and maintain that the dye simply diffuses in the water contained in the cotton, and that the dyeing process comes to a standstill as soon as the osmotic pressures in and outside the fibre have attained to a state of equilibrium.

At the outset, Witt's hypothesis is beset with numerous improbabilities, as will be readily seen, if we apply it to the dyeing of a developed diamine black upon cotton. In the first instance, according to Witt, diamine black would form a "rigid solution" with the cellulose. This being so, the subsequent diazotizing and developing baths can only be of any use, if cellulose is also capable to dissolve nitrous acid, and all the innumerable phenols, naphthols, aromatic bases, and their derivatives. Moreover, if we take into account that by treatment with the salts of barium, zinc, nickel, cobalt, iron and copper, benzidine dyes dyed on cotton can be quantitatively converted into their respective lakes, we must needs assume that all these salts are likewise soluble in cellulose. As a matter of fact, we would have to conclude that whatever substance is soluble in water, appears to be soluble also in cellulose. Witt himself will probably admit that this necessary consequence of his theory is nothing short of a monstrosity. It can, however, be shown experimentally that it is the water contained in the cellular cavities of the cotton and not the cellulose itself which acts as the solvent for the benzidine dyes. It is obvious that if Witt's explanation is correct, cotton or cellulose which is free from water and incapable to absorb any, should take up the benzidine dyes even easier than ordinary cotton.

Dinitrocellulose is manufactured at present in such perfection that it cannot be distinguished from loose cotton, and even the structural differences which are observed under the microscope are very slight indeed. This dinitrocellulose can be dyed with benzidine dyes exactly like ordinary cotton. By adding dinitrocellulose to acetone, solution ensues immediately and by pouring the solution on glass plates and allowing the solvent to evaporate, thin films of dinitrocellulose are obtained. Of course every trace of the cellular build of the cotton has disappeared and with it the water inclosed in these cells. In trying to dye these structureless films of dinitrocellulose with these benzidine dyes, we find that even after hours' boiling these films are as white as ever and indeed never take up the faintest trace of these dyes. This shows that in one and the same dyebath dinitrocotton is dyed to a bright shade, while dinitrocellulose remains colourless. The former possesses cellular cavities, either containing water or at any rate capable of being filled with water, dinitrocellulose of course does not contain any water, nor is it capable to

\* Except for the most delicate shades.

absorb water or to retain it. This leaves no doubt that the dye is located in the cellular cavities of the fibre and not in the substance of the latter. Exactly the same of course holds good for cotton itself.

From this I conclude that in this dyeing process the cellular cavities of the cotton are filled with the hot, more or less concentrated solution of the dye, and on cooling the skein, the dissolved colouring matter separates out more or less completely as a fine coating of colouring matter upon the walls of those cellular cavities. After drying the skein so dyed, its residual moisture depends entirely upon atmospheric conditions, but represents always a fraction only of the water required to keep in solution the colour deposited within the fibre. Even then, it appears, is the presence of water essential for the brilliancy of the dye. This is clearly seen if we deprive such a dyed skein completely of its moisture, either by subjecting it to heat, or by immersing it for a few minutes in absolute alcohol. The dye assumes in every case a dull or even dirty, and always surprisingly weak shade. Not infrequently can it be observed that the dye so treated altogether changes its shade, which is due to the fact that several benzidine dyes possess a different shade in the hydrated, than in the anhydrous state. It is a well-known fact, which has frightened many a dyer, that cotton dyed with diamine black R O assumes a dull maroon shade on the hot dyeing cylinders, but acquires its blue-black shade again as soon as the fibre has recovered its natural amount of moisture, on exposure to the air.

A further confirmation of the conclusions above arrived at is to be found in the microscopical aspect of cotton dyed with benzidine dyes. We observe numerous fibres the cellular walls of which are perfectly colourless, while the central canal appears more or less filled with colouring matter. This is particularly clearly visible in cotton dyed with benzopurpurin and immersed in absolute alcohol. The position of the dye is still better defined after treatment with acids, and observation between crossed Nichols. That this particular location of the dye cannot be distinctly observed on each particular fibre fragment is not to be wondered at. The cellular walls of the cotton are laterally perforated by an enormous number of very fine canals, and any colouring matter accumulated in these perforations, naturally will cause the appearance as if in certain parts the substance of the fibre itself was dyed through.

The view of the nature of cotton, substantively dyed, with benzidine dyes, which I have put forward above, makes the surprising readiness with which these dyes, upon the cotton fibre, can be subjected to numerous reactions a matter of course, while in the light of Witt's hypothesis it must appear quite puzzling, and requires the assumption of quite a monstrous dissolving power of cotton for compounds of every description.

In the above, I believe to have furnished conclusive proof, first that the benzidine dyes exist in the cotton in the free state, and not in the form of lakes, and further that the dyes or their solutions are occluded in the cellular cavities of the cotton fibre. This, however, does not explain, why only a limited number of acid dyestuffs are capable of dyeing cotton direct. That the diphenyl residue has nothing to do with this property, we have already seen, and indeed numerous dyes are known, which, although containing the diphenyl residue, do not possess the properties of a direct dye.

Now, it is evident that if the dyeing process in question is not a selective solution process, as Witt contends, but a phenomenon of diffusion as I suggested above, it must be possible to discover material differences between the constants of diffusion of acid dyes dyeing cotton direct, and of acid dyes not possessing that property. Up to now I have been able to examine, in this respect, a comparatively small number only of acid dyes, including benzidine dyes, but without exception it was found that the direct-dyeing dyes possess exceedingly low diffusion coefficients, while those of the ordinary acid dyes are invariably very high. It was further observed that of two direct dyes the one possessing the smaller diffusion coefficient, has the greatest avidity for the cotton fibre. Likewise did it become unmistakably evident that in the ordinary acid dyes a decrease of the coefficient of diffusion is invariably marked by an increase

of the capability to dye cotton. The complete series of these most interesting, and, I believe, also technically very important experiments, will be brought before this society at some future date.

At first sight the above observation appears strange, if not even improbable, it being by no means obvious why the dyes with the smaller diffusion coefficient should be the better cotton dye, considering that the ease with which a dye penetrates into the cotton increases with its diffusive capability. Indeed it can readily be shown that benzidine dyes penetrate very much slower into the cotton fibre than any of the other acid dyes. But the diffusion of the latter out of the cotton takes place quite as readily, while the slow diffusion of the benzidine dyes into the fibre, corresponds an equally slow diffusion of the dye out of the fibre. This is at the same time the explanation of the disagreeable "bleeding" of these dyes in washing, and which never ceases as long as there remains any dye in the fibre.

We are now in a position to give a complete definition of the process of direct dyeing with benzidine dyes, by describing it as *an aqueous solution of a dye of very small coefficient of diffusion, formed inside the cellular cavities of the cotton fibre by means of a dye-bath possessing a high osmotic pressure. The fastness of these dyes, as regards their "bleeding" off the fibre, is proportionate to the inertia of diffusion of these dyes and inversely proportionate to the magnitude of their diffusion coefficient.*

From the above it naturally follows that if by some means we could lower the diffusion coefficient of any of the ordinary acid dyes, this dye should now behave against cotton like one of the benzidine dyes. Without anticipating the results of my investigations on the comparative rate of diffusion of the coal-tar colours and the relation of this function to their constitution, which I intend to treat in a future paper, I may say that I found a very simple and ready means to considerably retard the rate of diffusion of a great number of dyes. This means consists in their conversion into barium salts. By converting croceine 3 B into its barium salt, we obtain a product which is fairly soluble in water. The diffusion coefficient of this salt is very much smaller, as the one of the sodium salt, which is the commercial form of the croceines. By making now a comparative dye test with the quickly diffusing sodium salt and the slowly diffusing barium salt, employing neutral bathis as in dyeing with the benzidine dyes, we observe very soon a marked difference between the two skeins under operation, a difference which is increased to a surprising extent, on the skeins being subsequently washed. The skein dyed in the solution of the sodium salt assumed a pale pink shade only, the skein dyed in the solution of the barium salt shows a deep, bright scarlet. This is a direct proof for my contention that *the capability of an acid dye to dye cotton like a benzidine dye is only a function of the coefficient of diffusion of the acid dye.*

The above-described method to reduce the rate of diffusion of an acid dye may, in some instances, be capable of advantageous practical application. In the present paper it was not my endeavour to arrive at any results of immediate practical bearing, but rather to contribute to the consistent and rational development of a theory of dyeing, which not only satisfactorily explains all the phenomena observed in dyeing, but will also prove itself a useful tool for further research, whether of scientific or practical purpose. Of course it might be objected that in the above arguments the behaviour of the silk fibre has not been taken into consideration. This omission is, however, intentional, and appeared advisable to me on account of the very vague nature of our present knowledge of the constitution of silk, under which circumstances it seemed to me rather hazardous to build conjectures upon such a doubtful basis. Witt's hypothesis rests largely upon the properties of dyed silk, and the behaviour of silk against dyes, but most of his arguments are merely analogies, the conclusive power of which is somewhat doubtful. This applies particularly to the inordinate importance this author attributes to the fluorescence certain dyes show upon the fibre. The state of solution of a dye, and any fluorescence it may exhibit, do not by any means bear such a simple relation to each other, that the appearance

of the latter could be said to imply the coexistence of the former. A boiling solution of rhodamine shows no fluorescence, but the latter appears on the cooling of the solution. Applying Witt's argument to this observation, we would have to assume that the hot solution is not a solution of rhodamine, on account of the absence of fluorescence. The phenomenon of fluorescence is obviously of a very complex nature, as it depends upon the molecular condition of the fluorescing substance, the temperature, nature of the solvent, colour of the light, and the presence or absence of other compounds. We further know substances which show fluorescence both in the solid state and in solution, whilst other compounds show most exquisite fluorescence in the solid state, but not a trace of it in solution. Such a complicated phenomenon like fluorescence, which itself requires explanation, is scarcely a suitable means for the explanation of other matters of doubt. For the rest I believe that it will be possible to explain even the dyeing of silk from the same elementary principles which I employed above in regard to wool and cotton.

#### DISCUSSION.

The CHAIRMAN remarked that the section was much indebted to Dr. Weber for coming from Manchester to give his paper on the chemical philosophy of dyeing, and invited comments upon his papers from the members present, especially those interested in the theory or practice of dyeing.

Mr. RAWSON said that Dr. Weber's theory of substantive dyeing was both novel and plausible. He asked if any steps had been taken to ascertain whether, in the case of benzidine dyes, an acid was liberated by the decomposition of the dye. In the case of wool dyed successively scarlet and magenta, Dr. Weber had quoted, as evidence that a compound had been formed with the wool, the fact that the dye was not removable by alcohol; but was it not possible that the magenta was fixed by the scarlet, notwithstanding the fact that the compound away from the fibre is soluble in alcohol.

Mr. RICHARDSON said that the paper was an important and valuable one, and the author was obviously awake to other theories than his own. He thought that silk might very well be used for experiments such as those described in the paper, for he had himself shown that it contained  $\text{NH}_2$  and  $\text{COOH}$  groups in about equal proportions, but no aldehyde group. The absence of this group would lead him to expect that the silk fibre would not stain blue with ferric ferriyanide; was he right in supposing this? (Dr. WEBER: Yes.) Also had Dr. Weber experimented on artificial silks, the nitro-celluloses and their recent non-combustible products?

Dr. LEWKOWITSCH thought that Witt's theory of solution had been propounded largely because Van't Hoff's ideas happened to be in the air at the time. Dr. Weber had suggested that, in benzidine dyeing, the migration of the dye into the water of the fibre was due to the addition of salt to the solution in the vat; why should not the salt equally diffuse in, and hinder the entrance of the dye?

Mr. PROCTER said that Dr. Lewkowitsch had to some extent anticipated him. He was not clear that osmotic pressure could take the colour into the water in the cavities of the fibres, since the salt would probably diffuse in at least as rapidly as the colour. Probably in dyeing as in tanning, the colloid character of the fibres themselves had much to do with the observed phenomena.

Mr. ALFRED WHITAKER said that he had noticed that a small piece of cloth dyed with a benzidine dye did not bleed when held under a tap, whereas a larger piece on a roll did. He wished to know why was it that crocein-scarlet would not stand washing whereas beta naphthol if diazotised and developed with para-nitraniline would? Would it be possible to pad benzidine-chloride mother liquor on cloth, diazotise, and develop it in the same manner and so get a fast colour?

Mr. ALFRED WHITAKER, called the theory put forward by Dr. Weber would seem to account for the fact of very strong baths being necessary in the dyeing of benzidine colours.

Dr. WEBER: Yes, and also of the bath being left unexhausted.

Mr. ALFRED WHITAKER, proceeding, wished to know if any method of fixing such colours in the fibre had been found by Dr. Weber. It was easy to get goods to a certain depth of shade, but after this point no greater depth of colour could be obtained. This also bore out Dr. Weber's theory; but by means of alternate baths of colour and fixing agent (if such had been found), it might be possible to get such deep shades on the goods as was now impossible.

Dr. WEBER, in reply, said that he had never, in the case of cotton, looked to see if any decomposition, with liberation of free acid, had taken place. It would, however, have been indicated by a colour change, the acid corresponding with Congo red being, for example, Navy blue in colour. The criterion as to the existence of an acid in the free state or combined lay in its ability to form a lake, or not. As to the case of successive dyeing alluded to, it was true that Chrysamine was insoluble in alcohol, but he had been dealing with wool-scarlets, the lakes of which with basic dyes are soluble. He quite agreed with what had been said about the silk fibre; at the same time the wool fibre had one advantage that silk did not possess,—it yielded decomposition products, e.g., laugenic acid, which had the same capacity for dyeing or forming lakes as the wool itself. Artificial silks he had not experimented with, having found it impossible to reduce their  $\text{NO}_2$  groups to  $\text{NH}_2$  groups. As to the process by which the dye was taken up, the fibre when placed in the dye-bath became filled with water and then acted as a dialysator, the (crystallised) dye diffusing until its osmotic pressure inside the fibre was equal to that in the solution outside, the maximum had then been reached, and no more dye could be taken up. It was for this reason that a benzidine bath could never be exhausted. Crocein washed poorly because it had a high coefficient of diffusion; para-nitraniline washed well because it contained no lake-forming groups, and so could form no sodium salt that might diffuse; it was a pigment, not a substantive dye. The difference in the fastness for washing observed in dyeing with one and the same direct dye was due to the relation between the shade produced and the concentration of the dye-bath. You might dye to a certain shade by boiling for 40–60 min. in a bath till the maximum of coloration was obtained, and you might also get this shade by boiling for a shorter time in a stronger bath, but the colour was not so fast in this second case as in the first. There was a great future for direct dyeing by means of the "developed" dyes, but it was a delicate process, and necessitated the use of ice, which was expensive in this country. There would be a much greater use for benzidine dyes if they could be made fast; on cotton they were not fast, not being there as lakes. It was no use to look for metallic mordants; copper had been tried, but the colour was spoiled by soap. The only way was to find an organic compound of an albuminoid nature that would form a lake with the dye. Laugenic acid would do this, but was too expensive. The author had himself obtained such a lake, of benzo-purpurin with an albuminoid substance derived from cotton; it was deposited as a slimy film in a bath that had been used for some weeks, but its true nature was as yet undetermined for it had not been found possible to decompose it either with acids or with alkalis.

## Glasgow and Scottish Section.

Chairman: R. Irvine.

Vice-Chairman: E. J. Mills.

Committee:

G. Beilby.	W. I. Macadam.
W. J. Chrystal.	J. S. Macarthur.
J. Clark.	T. L. Patterson.
C. J. Ellis.	J. Pattison.
G. G. Henderson.	J. B. Readman.

R. Irvine.	D. R. Stewart.
J. Falconer King.	R. R. Tatlock.

Hon. Secretary and Treasurer:

J. Stanley Muir, Chemical Laboratory, University of Glasgow.

Members who desire to read Papers, exhibit Apparatus, &c., or introduce Discussions during Session 1893-94 are requested to give early notice to the Hon. Local Secretary.

### SESSION 1893-94.

Glasgow:—

March 6th:—

Mr. James F. Techer. "Oil Gas."

Prof. E. J. Mills and Mr. W. Macfarlane. "On the Oxidation of Aniline."

May 1st.—Prof. E. J. Mills and Mr. Saweis. "On the Action of Alums on Gelatin."

Edinburgh:—

April 10th.—Dr. J. B. Readman. "The Effect of the Saline Constituents of Water on the Character of Beer."

Meeting held Tuesday, February 6th, in the Philosophical Institution, 4, Queen Street, Edinburgh.

### MR. R. IRVINE IN THE CHAIR.

THE CHAIRMAN, before beginning the business of the meeting, called on the Secretary to read a resolution expressive of the thanks of the Section to Mr. Fawsitt, the lately retired Chairman.

THE SECRETARY read as follows:—

"The committee and members of the Scottish Section of the Society of Chemical Industry record with sincere regret their acceptance of the resignation of Mr. Chas. A. Fawsitt, who has for the past 18 months so ably and indefatigably acted as their Chairman of Section. They cannot allow the occasion to pass without expressing their warmest thanks to him for the success which has attended the meetings of the Section during his tenure of office."

THE PRESIDENT, in moving the adoption of this resolution, said that Mr. Fawsitt had tendered his resignation of the Chairmanship of Section, because he considered that a chairman resident in Edinburgh would be better able to further the arrangements for the Annual Meeting of the Society in Edinburgh in 1894. In accordance with Mr. Fawsitt's desire the committee had accepted his resignation and had unanimously elected Mr. Robert Irvine to the vacant post.

The resolution was unanimously adopted and the Secretary was instructed to forward a copy of the minute to Mr. Fawsitt.

THE PRESIDENT then took the chair.

### THE PRESIDENT IN THE CHAIR.

## ON THE PREPARATION OF CARBON BLACKS FROM NATURAL GAS IN AMERICA.

BY GODFREY L. CABOT, BOSTON, U.S.A.

THERE is a certain small industry peculiar to the United States, of which, I think, no accurate account has yet appeared in any scientific journal or standard technical work, and which I am therefore encouraged to bring to your notice in the hope that it may at least have the charm of novelty to most of you. I refer to the manufacture of lamp black from natural gas. The substance thus obtained, known to the trade as carbon black, and also less frequently as hydrocarbon black, gas black, satin gloss black, jet black, silicate of carbon, and various other names, is collected on the under side of cast-iron plates or rollers, from which it is automatically removed by suitable scrapers of iron or steel. This gas is burned from gas jets such as are used for illuminating gas.

As is the case with so many more important inventions, the merit of discovery has been claimed by different people and belongs to no one alone.

The first person who collected soot on a surface thrust into a flame made carbon black.

For the purpose of this sketch, however, the industry may be traced to certain printing ink makers in Philadelphia and New York, who found that soot thus made by artificial gas gave a beautiful gloss and intense colour to printers' ink, differing totally in both of these respects from the lamp black obtained in the ordinary way by burning oily or resinous matters in an insufficient supply of air, allowing the smoke to settle in deposition chambers. A small amount was thus made in a private way at an expense of 2.25 dols. to 3.1 dols. per lb., till in 1872, or thereabout, Peter Neff, of Ohio, and Messrs. Haworth and Lamb, of Massachusetts, made experiments with natural gas for the same purpose, and the two latter erected in New Cumberland, Pennsylvania, the first factory in which carbon black was successfully made on a commercial scale. Others soon followed, too numerous to name, seeking thus to utilise the natural gas which was at that time going to waste in enormous quantities. This gas is always found with petroleum, and for many years it was chiefly regarded by the unscientific men who controlled the oil industry as a dangerous nuisance to be blown off and got rid of in every possible way.

The amount of this valuable and irreplaceable substance which has been thus utterly wasted, it is impossible to estimate with any approach to accuracy, but I think I am perfectly safe in saying that it may be measured in hundred of trillions of cubic feet. I myself have a well from which probably three billions of cubic feet of gas was wasted before any was utilised. Here, then, was an industry of which the raw material was natural gas, and the finished product easily paid for transportation over the worst roads.

The amount of capital required to start the business was comparatively small, and the price of the black high. The result was a crop of small concerns, most of which perished after a short existence.

Experience soon showed that the quality of the gas and its adaptability for making black, varied greatly in different localities; that the duration of the supply was very uncertain; and that the average uneducated man, even though backed by Yankee push and ingenuity, did not possess the requisite engineering or business ability to invent, erect, and maintain in successful operation the requisite machinery, nor to obtain and keep the requisite amount of trade.

The first factory erected contained a series of flat-bottomed cast iron pans arranged in rows and filled with water, which was supposed to improve both the quantity and quality of the black. Under each row of pans was a line of burners, ordinary gas tips, the flame of which impinged upon the iron and thus deposited the black. At intervals of 20 minutes a car travelled from one end of the row of plates to the other, supported on rails and drawn by a wire

rope, and a scraper fixed in the open top of this ear or travelling black box removed the black, which fell into the bottom of this ear, and was thence removed by hand, bolted, and packed in barrels for market.

Of all the factories that have since been erected perhaps no single one has used gas capable of producing so much black per thousand feet or of so soft a quality, and if there were any of this black still for sale, small quantities of it could be sold for four or five times the present market price.

The first lot of 500 lb. put on the market was sold for 2.50 dols. per lb.; the next 1,000 lb. brought 1.50 dols., and the factory paid for itself in three months. A year's output was soon contracted for at 1.25 dols. per lb., but as competition increased the price rapidly fell. By 1881 black was selling at 35 c. per lb.; by 1882 at 31 c.; in 1883 an offer of 24 c. per lb. for a 2,000-lb. lot was refused. Meanwhile various other methods of manufacture came into vogue. Many manufacturers tried cooling the depositing surface with water in various ways and all abandoned it, including the original factory, it having been proved that no material advantage was thus gained, either in quantity or quality, and an additional complication and expense, involving considerable, mechanical difficulties were thereby introduced. At first the great object of the manufacturers was to obtain the most intense colour, and the greatest gloss, and in this respect the original brand was soon surpassed, but at the expense of softness and opacity.

All carbon blacks bear a general family resemblance; are very intense in colour; glossy whether rubbed in the dry or in varnish; have an extraordinary mixing strength, which, however, varies greatly and compares differently with lamp black according to the medium in which they are ground with the diluting pigment, i.e., whether water, oil, varnish, or what not. Generally speaking, carbon black ground in oil with 100 times its weight of white lead gives a very dark grey, showing about three times the strength of a good lamp black and from five to ten or more times the strength of the poorer blacks.

They take twice as much oil to make a varnish of a given consistency as do ordinary lamp blacks, but are much harder to mix, harder to dry, and more apt to curdle or form clots.

All carbon blacks will mix with water by simply shaking them with it; lamp blacks, generally speaking, will not, and this is a convenient way of determining, in cases otherwise doubtful, whether a black is lamp black or carbon black.

The process originally used by Messrs. Haworth and Lamb is still in use at Sayenburgh, Butler County, Pa., by their successors, Messrs. Nolen and Boardman. Peter Neff, of Ohio, was the next to enter the field, using a process somewhat similar to the first. His gas came from the geological horizon known as the Berea grit, and was poor in quality for the purpose of black making. He used no water, and shaped his benches slightly concave below, a doubtful advantage. His was the only factory for carbon black ever operated in Ohio, and never exceeded an output of 125 lb. a day. It has not been in operation for two or three years or more.

The next process in point of time was the roller process, in which the collecting surface is a cylinder revolving on its axis. Various patents were taken out, and two or three factories were put in operation on this principle. It is very expensive both in cost of plant, repair, and consumption of gas, but is still used in one factory, and the black can be sold in small quantities at a high price.

When carbon black sold at 60 cents a lb., it was thought by many that if it ever became equally cheap it would replace the higher grades of lamp black made from oil, and, to a certain extent it has; but there are some uses for which lamp blacks are preferred, and there are brands which have remained practically unchanged in price for twenty years, and have increased the sale, at a price much higher than that of carbon black now.

Meanwhile the output of carbon black has been increasing at a very rapid rate with a downward tendency in the price. In 1881 there was probably made from 400,000 to 500,000 lb., all of it on various modifications of the bench principle and the roller principle. In 1883, a new mechanism

attained commercial success—that, namely, of a large plate, 24 feet in diameter, pierced with holes for ventilation, and revolving over stationary burners, and a stationary scraper, and a black box beneath it, from which last the black was removed by screw conveyers, and thus carried to the bolt, a cylindrical revolving sieve, through which the black fell to the bin beneath, from which it was lifted and packed by hand.

This machinery took the place of labour in sifting the black, and the loss in handling, due to the extreme lightness and fluffiness of the black, was diminished. As it comes from the sieve, the black is an extremely light, fine powder, weighing less than 5 lb. to the cubic foot. A gentleman, in conversation with a friend of mine, dipped his finger into a barrel of this unpressed black without noticing he had done so till his attention was called to it.

It will sometimes oscillate in waves at most like water, floating, as it were, on the air, which it mechanically imprisons. This may partly be due to its electrical condition from the friction of the scrapers working at a high temperature of 300° C. on a perfectly dry surface. The black is easily affected by electricity. If you rub sealing-wax smartly on the sleeve and pass it over the black, it will fly up as it caught by a baby eclone.

It is so dry and fine that I have seen it fly through a hole no bigger than a steel knitting needle, just as sand falls in an hour glass.

To transport it to Europe, or even shorter distances, it is necessary to compress it, which is a tedious and difficult job, far more so than with ordinary lamp black. The first successful packer was a screw press, worked by hand. To compress the black it was necessary to expel the air, and the difficulty lies in preventing the black spitting up with the air, which may be accomplished by covering the plunger of the press with a sheepskin, woolly side out. The wool retains the black, but permits the air to escape. A very important point is to shield the black from all air currents, from the time it is removed from the plates till it has been packed.

A slight air current will float away a considerable amount of black, causing loss and a nuisance.

In the years 1884 and 1885, small cast-iron rings, rotated spasmodically by a ratchet mechanism, came into use as depositing surfaces. These are 3 ft. outside diameter, 2 ft. inside diameter, and have a ring of gas jets underneath them. This process was the invention of Mr. A. N. Blood, since dead. By it, one half of the total output of carbon black is at present made. It is customary to put these in rectangular buildings, dimly constructed of sheet iron and steel, each containing 84 such rings in six rows, all actuated from a shaft outside the building.

The best output yet obtained is about 1 lb. per 1,000 ft. But I think there is at present no factory that reaches this average, and some not one-fifth of this.

Another process that has established itself, after five or six years of costly failure, is upon plates 24 ft. or so in diameter, with gas flames and black box rotating beneath it. Another process, introduced in the year 1891, and in use at one of the two largest factories, consists of a series of small, independent, rectangular plates, with a scraper moving back and forward under each by a reciprocating motion. It is a noticeable fact that mechanical success or failure has depended more upon the skill with which the different methods have been applied than upon their inherent excellence.

Since 1885 most of the factories have been so arranged that the black is handled wholly by machinery. From below the bolt it is raised by an elevator to a large bin, out of which it is packed by machinery. An automatic modified flour packer, working on the principle of a screw propeller, has now come into general use.

In 1886 the production reached 900,000 to 1,000,000 lb., and the price had sunk to 8 cents, although much was still sold at higher figures.

In 1889 some lots were sold that only netted the producer 3 cents. Since then the price has been better, netting the producers perhaps 7 cents a pound at their factories, on an average, for the last three years.

The output has meanwhile increased to about 10,000 lb. per day, and will amount this year to fully 3,000,000 of pounds.

The uses of the black are for printers' ink, paints, mineral black stove polish, shoe leather, rubber goods, fertiliser, colouring cement, mortar pulp and artificial stone, harness oil, stenciling, mixing with other blacks, such as lamp black, ivory black, &c., to improve their colour.

Chemically speaking, they contain 92 to 93 per cent. of carbon, 5 to 6 per cent. oxygen, and 1 to 2 per cent. hydrogen, and no trace of any mineral matter, nor have I ever known of gas black being adulterated, which I think is much to the credit of the trade.

*Description of Apparatus for the Production and Collection of Carbon Black from Gas.*

A circular plate of cast iron 24 ft. in diameter A, cast in 18 pieces and carefully levelled, is hung to a 16 in. mast B, a 3½-in. double extra strong tubing by guy wires C, tapped into a cap at the top of the mast and adjusted as to length

by twin buckles C. Beneath these, supported on pulleys at the foot of the mast and balanced by ties running horizontally to a collar on the mast, revolves once in the 15 minutes or so a framework driven by a chain D at its circumference, and carrying a black box and scraper E, a track of angle-iron for the chain to lie upon, and a gridiron of 1½-in. pipe with from 700 to 1,400 gas burners such as are used for illuminating purposes F, is supplied from a 4-in. O D feed line placed as near the middle of this gridiron as the mast, &c. will allow, and looking like the backbone of an unsymmetrical skeleton G.

This feed line takes its gas in turn from a 1½-in. pipe I, from a gas box rotating on a central mast, which is fed with gas from below. In the rotating black box is a screw conveyor H, actuated by a pinion at the inner end J, that engages in a small bevel box fixed on the mast. The black discharges downward from a spout into a circular trough-like box K, shown in section in accompanying sketch, and from here it falls through a hole in the bottom into a long conveyor that carries it to the elevator L, when it passes through a bolting machine made of very fine wire cloth, and

is then packed by machinery. On the circular box above reverted to, rotates a cover M, and two cardinal points are to be noted:—

1st. No draughts of air must touch the black at any stage of the manufacture.

2nd. It is made and handled wholly by machinery up to the time that it has been packed; thus a uniform machine-made black of excellent quality is obtained.

## NOTE ON THE ABOVE PAPER.

BY ROBT. IRVINE.

This manufacture is an adaptation of a process well known in England long before the discovery of natural gas in connection with the American oil wells. The same quality of black was made with similar apparatus, although on a much smaller scale, by printing-ink manufacturers here 30 years ago, who employed ordinary town gas for the purpose. My own experience confirms Mr. Cabot's as to the quantity of gas required to produce 1 lb. of black. Burning 1,000 ft. of gas per hour the produce never exceeded 1 lb.; and, of course, considering the price of town-made gas, this meant a first cost of at least 5s. per lb. on the black produced.

This beautiful substance, with its velvet-like gloss, is quite different in appearance from lamp black made by burning oils. But as regards *colour value* or covering power, there is between the two not the difference Mr. Cabot asserts. When the two varieties are reduced with, say, 100 per cent. of zinc oxide or chalk, the shade given shows very little difference between the two in colour value.

Of course any idea of foreign competition with this American manufacture is out of the question, and America will hold the field until her resources of natural gas are exhausted.

With regard to the matter of price. Taking 7 cents a lb. as the lowest price at which gas black can be delivered with profit in this country, as compared with the cost of black prepared from heavy dead oils (which yields 15 per cent.), we have the oil black at a cost considerably less than the gas black as at present imported.

Both of these blacks are contaminated by such bodies as chrysen and pyrene, which are of dirty brown colour; these dissolve in the varnish used for the manufacture of printing ink, and are apt to communicate this to the printed matter, and in process of time shows a kind of halo surrounding each letter. This is especially noticeable in old books or filed newspapers. These impurities can only be eliminated by igniting or calcining the black at a red heat.

It has often been suggested, and I believe has been tried experimentally, that the gas from the shale retorts in the oil manufactories in Scotland could be profitably employed for this manufacture; but considering the enormous quantity of gas required to produce this black it is most probable that the shale gas can be more profitably employed as fuel.

The PRESIDENT said that this process was obviously only applicable where gas could be obtained for nothing. Even Glasgow gas at 2s. 6d. per 1,000, and containing more carbon than Edinburgh gas, would not pay to burn for the manufacture of carbon black.

The form of press employed in packing this black was of interest, and he asked Mr. Irvine to further explain its method of use.

Mr. IRVINE said that the light substance was first put into a barrel capable of sustaining a level pressure, and in place of using an ordinary piston, such as would be employed with a coherent substance, the front of the piston was covered with a sheepskin the wool side outward. The wool allowed the air to escape but retained the solid black. The press worked admirably. Impressed black was so light that a large feather-bed tick filled with it could easily be lifted with one hand.

Dr. MARSHALL asked if blacks were made from poor coal gas enriched with the vapour of light oils.

Mr. IRVINE said that a process on that principle was being worked out at present and had been covered by patent.

Dr. READMAN asked whether it was possible to extract the oily impurities by means of solvents.

Mr. IRVINE said that although possible such a process would be too expensive, owing to the difficulty of handling so extremely light a material. By calcining this impure black the objectionable impurities were completely eliminated with a loss of about 15 per cent. of black.

## ON THE PRESENCE IN PAPER OF RESIDUAL CHEMICALS USED IN ITS PREPARATION.

BY ROBERT IRVINE, F.R.S., AND G. SIMS WOODHEAD, M.D.; F.R.S.E.

The simultaneous removal of excise restriction from the manufacture of paper, and the publication of newspapers form an era in the Victorian age, and the effect which followed was marked by the great increase of newspapers and their circulation, causing an extraordinary demand for increased supplies of paper.

Thirty years ago, most (if not all) of the paper produced in Great Britain was manufactured from rags; the process then obtaining being the simple and homely one of boiling with weak leys of soda, followed by the use of bleaching materials in very limited amount. Paper was then practically made up of pure fibre interwoven or felted together. Now cheap papers are a peculiar compound of China clay, stucco, and resin, held together by a skeleton of fibrous material obtained from wood, esparto grass, or straw, from which the fibre is eliminated only by drastic and costly chemical treatment. Had these new raw materials not been at hand, the rag supply of the world would have been insufficient to meet the present wants of Great Britain alone.

As a natural consequence paper fell in price, and expensive chemical operations necessitated the use of cheap loading materials as compensation—whilst the careful but tedious washing of the fibre or half stuff had either to be partially or wholly done away with.

It is unnecessary for our purpose to enter into the details of this great industry; but a very brief sketch of the modern processes in use will enable us to point out some of the dangers to the stability of paper thus introduced.

*Raw Materials.*

Esparto grass, wood pulp, and straw, are now practically the materials used in the construction of paper.

At the present day large quantities of the two former are imported into this country. Esparto, a grass from Spain and the north of Africa; wood in the form of dried pulp, prepared principally in Norway, Sweden, and Germany, by acting on it with sulphurous acid and sulphites (and the so-called sulphate of soda), also in some cases by the use of caustic soda. This is supplied to papermakers in a dry condition in the form of coarse thick sheets of a light brown colour.

The esparto or grass consists of a fibrous core surrounded by a sheath of silicious and gummy matter, which is firmly attached to the central portion, and to remove which chemicals (usually caustic soda) are plentifully used, the amount required being generally 10 per cent. of the weight of grass employed.

### Boiling.

During the boiling process much of the gummy and silicious matter is removed by the alkaline lye, to which it gives a deep brown colour, while at the same time a portion of the more delicate fibrous matter of the grass is destroyed. (In the case of wood fibre prepared by the sulphite process this treatment is not required.) The boiled material or stuff is reduced to a fibrous magma by suitable machinery; at the same time the yellow colouring matter and the soda are removed as far as possible by washing, but this is often so incomplete that from 1 to 2 per cent. of soda may be found in the washed stuff previous to the

### Bleaching Process.

For this purpose chlorine, in the shape of a solution of chloride of lime, is employed, in quantity varying according to the quality of the material, but the amount is never less than from 3 to 4 per cent. (equal to from 8 to 10 per cent. of dry bleaching powder) of the grass used, and sometimes even more. The action of this bleaching agent is sometimes accelerated and increased by heat or by the addition of sulphuric acid to its solution which sets free chlorine and its oxidation acids, the bleaching operation thus being performed very quickly (here also there is a definite loss of fibre). The entire removal of such an amount of chlorine from the bleached pulp by washing is a most tedious and difficult operation and requires an extravagant amount of water such as few ordinary mill supplies could afford. On the other hand, if the chlorine compounds are not entirely removed from the pulp the destruction of the paper within a brief space of its manufacture is certain, hydrochloric acid being formed by a partial breaking down of the cellulose which destroys its texture. This was a common enough occurrence when the increased demand sprang up consequent upon the remission of the duty, and when thus carelessly prepared the finished paper after being stored for some time became brittle and so lost its textile qualities, falling to pieces on being manipulated, a serious enough matter in a pecuniary sense for the paper maker, but unfortunately much more so in effect when such paper was used for printing valuable books.

To remedy this evil, advantage was taken of the property hyposulphites possess of decomposing hypochlorites. This cheap material could be more profitably used by the paper-maker than the enormous waste of water required to remove the last traces of chlorine from the pulp. Indeed the general practice which obtains in the present day often merely provides for getting rid of the chlorinated water from the bleached half stuff by pressing out that which can be removed in this manner and then adding antichlor; subsequent washing with water being either very partial or in some cases almost wholly dispensed with.

We have therefore in many bleached paper pulps the products derived from the action of hyposulphites upon the chlorine compounds, these consist principally of chlorides and sulphates which are in a general sense innocuous, but there is also a notable proportion of finely divided sulphur separated in the process which is precipitated and becomes entangled in the fibres and is thus transferred to the finished paper. The pulp at this stage is generally alkaline owing to the presence of unsaturated lime in the bleaching solution.

### Sizing.

For this operation alum, or acid aluminous compounds in conjunction with resin soap is freely used. Printing papers may in consequence give a distinctly acid reaction. In some cases starch is added to the pulp, which during the drying of the paper gives it a fine glossy surface. In such papers it is not impossible that there may be organic acids formed as products of the decomposition of the starch in presence of the water which paper attracts to itself when exposed to the damp atmosphere of our climate, this water generally amounts to one-tenth of its weight.

To counteract the brown tinge which even well bleached grass or wood fibre always retains, ultramarine blue is added to the finished pulp, which (as already stated) is sometimes of an acid character. When this is so, it gives

rise to another source of impurity, the ultramarine being decomposed by the acid; sulphur compounds are set free, which are peculiarly disagreeable, owing to the formation of hydrosulphuric acid. In this case also sulphur is separated and is transferred to the finished paper.\*

The presence of sulphur and its volatile compounds in ordinary paper may be detected very simply.

A small quantity of the paper under examination (about 1 oz.) is placed in shreds in a glass flask and covered with distilled or rain water. The neck of the flask is loosely plugged with a coil of white blotting paper which has been previously soaked in a solution of (basic) acetate of lead and dried. Gentle heat is applied but the contents of the flask are not allowed to boil—a watch-glass is placed on the top of the plug—in a short time the blackening of the lead compound, owing to the formation of sulphide of lead, will show if sulphur, sulphides, or loosely combined sulphur compounds are present.

It is true the amount of sulphur is generally very small, varying from mere traces to 0.5 per cent. in good papers, although it may be present in greater amount in cheap flimsy newspapers where obviously it does no particular harm; but where such papers are used for printing books or pamphlets, it may give rise to most objectionable results.

The sulphur compounds derived from the use of hyposulphites when that substance is used as an antichlor and those from ultramarine are distinguished in the following manner.

By treating the paper with water alone as described, if sulphur or sulphides derived from hyposulphites are present the plug of acetate of lead soaked paper will become coloured by the sulphide of lead formed, rendering it faintly brown or black in colour according to the amount present. If no such coloration occurs sulphur or sulphides are absent as derived from hyposulphites.

Of course this test is only of value when papers are neutral or slightly alkaline. If the paper gives an acid reaction the hydrosulphuric acid evolved may be partly or wholly derived from the ultramarine used, but if the paper is neutral and has given no colour reaction to the lead paper when heated with water alone, if a few drops of acetic or hydrochloric acid be added to the contents of the flask colouration at once shows.

Some ultramarines are so unstable that even the carbonic acid present in a loosely combined or free condition in hard waters is sufficient to cause decomposition and evolution of hydrosulphuric acid.

When sulphur and linseed oil are brought into contact there ensues a distinct and well-known chemical reaction, the sulphur breaks up the oil and combines with its hydrogen, hydrosulphuric acid being set free.†

As one of the principal uses of paper is that of a printing medium, and as in all the higher classes of printing ink, linseed oil is used as a vehicle or medium for the black or other colouring materials used in its manufacture, if free sulphur or sulphides or volatile sulphur compounds are present, the infallible consequence of using such papers for printing purposes is the production of sulphuretted hydrogen and other like products which impart their characteristic and disagreeable odour to the resulting book or periodical.

We admit that even the most carefully prepared printing inks retain the odour of the materials used in their manufacture, but this is very trifling, and we have become accustomed to associate all printed matter with the not unpleasant balsamic odour of the press-room, which odour, however, has no relation to the fœtid and disgusting smell which is engendered when sulphur is present in the paper used.

These results seem forcibly to show:—

1. That the use of hyposulphites as antichlor, even when the antichlored pulp is thereafter thoroughly washed, is unsafe and a mistake.

\* Practical papermakers have realised, to their cost, the trouble free sulphur gives in corroding the wire cloth and the dandy rolls which form such an important and costly portion of the paper-machine. The sulphur combines with the copper of the brass wire tissue, forming sulphide of copper, and the wire gauze becomes rotten long before it otherwise should be.

† The so-called vulcanising of linseed oil by this means is a well established process in the arts.

11. That the introduction of ultramarine to "clear" the brown colour of the fibre is also unsafe when acid aluminous compounds are used in excess in the sizing operation.

Both substances under certain conditions obtaining in paper manufacture may introduce, proportionately as they are used, sulphur or sulphides into the paper, with the consequences we have mentioned.

The remedy seems simple, and we advise the substitution of sulphites or bisulphites or even sulphurous acid for hyposulphites, the same end being gained by their use, these reducing agents destroying the active chlorine compounds without sulphur being precipitated. We understand many paper-makers now use sulphites in place of hyposulphites.

The most perfect antichlor for chlorine bleached pulp or cotton cloth would of course be peroxide of hydrogen, could a cheap method of its preparation be found (there are indications that the present costly process may soon be simplified and cheapened), peroxide of hydrogen would then supersede chlorine, presenting as it does the most perfect bleaching agent known.

As regards the use of ultramarine, we would advise the substitution of Prussian or aniline blues (the latter of which, however, is a very unstable colour), which cannot under any circumstances give rise to the unpleasant odour of sulphuretted hydrogen emitted by ultramarine when acted upon by even weak acids. The increased cost of these colouring matters will be more than recompensed by their higher tinctorial value. It is true that the ultramarine supplied to paper-makers is of the most stable character possible to a pigment into the composition of which alkaline or earthy sulphides enter as an essential part, but it must in any condition be a source of danger alluded to.

More complex changes than these we have indicated may occur when paper containing starch and sulphur or its volatile compounds is used for printing purposes, and it is not impossible to suppose that evil-smelling bodies allied to the mercaptans may be formed, especially if the paper is in mass as in bound books and exposed to heat and moisture.

The whole question we have raised is one well worthy of most careful study. The evil we refer to has caused much trouble and inconvenience lately, more especially in connection with one of the most widely circulated periodicals of the day, the pages of which, sometime since, smelt very vilely. We investigated the matter, and the smell was undoubtedly traced to the presence of sulphur compounds in the paper used; not that this paper was specially bad in this respect, containing only 0.20 per cent. of free sulphur, yet in this case the general conditions favoured the evil. In the case we refer to hyposulphite had undoubtedly been used by the paper-maker (who simply followed the course of his forefathers) and where such anti-chlor is used sulphur must be one of the products.

Of the many samples of paper we have examined we have found "Scotch printings" very free from "antichlor sulphur," but almost invariably we have found all papers to contain a notable quantity of sulphides derived from ultramarine.

We have not referred to the existence of these evils in regard to the high-class writing papers, but we have no doubt they will be found to exist there also.

The smell of paper and printing ink has in the past been "put up with," but the taste of the reading public has now become fastidious in respect to the physical as well as the moral purity of their mental pabulum.

## Obituary.

### M. ALFRED SOLVAY

FOUNDER AND DIRECTOR OF THE SOCIÉTÉ SOLVAY ET C<sup>IE</sup>, MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY, MEMBRE HONORAIRE DE L'ASSOCIATION DES INGÉNIEURS SORTIS DE L'ÉCOLE DE LIÈGE, &c.

ALFRED SOLVAY was born in the year 1840 at Rebecq, in Brabant, Belgium. His inclination and tastes were towards agricultural pursuits, but his father, M. Alexandre Solvay, who was a merchant, an owner of quarries, and a salt manufacturer, decided that he should pursue a commercial career. Accordingly at the age of 20 he was placed first with a shipowner at Antwerp and subsequently at Hull. In 1862, his brother, M. Ernest Solvay, who, at Brussels, had commenced the industrial application of his now well-known ammonia process for the manufacture of soda, invited Alfred to join him. This invitation the latter at once accepted, and about the end of the year 1863 the Solvay Company was founded, with M. Alfred Solvay as its director. Thus post he retained up to the time of his death.

The first manufactory was erected at Couillet, and operations were commenced in 1864. In 1867 the firm was awarded a bronze medal at the Paris Exhibition.

The first-fruits of success as regards public recognition of the merits of the ammonia-soda process, were reaped by its originators at the Universal Exhibition of Vienna in 1873, when they were awarded a diploma of honour, and the attention of the manufacturing world may be said henceforth to have been definitely directed to this new departure in alkali-making.

After this the two brothers were engaged in starting large works in England and France in 1874 and 1876; in Germany in 1880, 1883, and 1885; in Russia in 1883 and 1892; in America in 1884; and in Austria in 1885. The organising of so vast an association, meant for Alfred Solvay, who was chiefly concerned therein, a problem involving in the highest degree the qualities of diplomatic judgment and tact.

In 1879, he resigned with great regret, the directorship of the works at Couillet, and went to live in Brussels, in order to devote himself, with his brother, to the general administration of the numerous works, which he had contributed to found, and set in operation. Their development he followed step by step, and visited them regularly in turn each year. In spite of all this labour, Alfred Solvay nevertheless found time to devote to public affairs, and, spite of his extreme repugnance to municipal official positions, he allowed himself to be chosen as "conseiller provincial" of the canton of Châtelet in 1878, and in the same year as "conseiller communal" of Couillet. In 1893 he appeared in the Senate as representative for the arrondissement de Nivelles.

In the year 1877, the distinction of "Chevalier de l'ordre de Leopold" was conferred upon Alfred Solvay, and in 1890 he was exalted to the rank of an officer of that order.

His decease took place on the 23rd of January last at Nice, whither he had gone for a few days' rest.

In considering the character and personal qualities of Alfred Solvay, it is necessary to turn to certain incidents in the development of the work of his life, during which they were called forth.

The advent of the new industry was encompassed with difficulties. Its development demanded all the energy, courage, and patience the two brothers could put forth, to attack and to solve the many technical and commercial problems which then arose.

To this end, however, one circumstance was particularly favourable. This was the extraordinary confidence established between the brothers, so differently gifted that the one might be truly said to be complementary to the other.

We have thus a picture of the one brother (M. Ernest Solvay) continually engaged in the conception of ideas, and planning of designs and schemes, whilst the other was continually striving to carry them into practical execution, thus leading to inevitable improvements, revision, and consolidation. The community of confidence and the brotherly forbearance necessary for development on such lines, could not but prove a source of great strength to the entire concern.

In the year 1892, Alfred Solvay founded the Bacteriological Institute of the University, in Léopold Park, and to this end he presented the sum of 100,000 francs to the city of Brussels.

This memoir should not be closed without some reference to the tribute paid to the deceased by his workpeople at Couillet, and embodied in a funeral discourse delivered in their name by M. Bruyère, one of their number. The following sentences are extracted from it:—

"M. Alfred Solvay was no ordinary master or patron; he loved his workpeople, and lost no opportunity of coming to their aid on any occasion requiring it. We likewise were happy at any time to testify our affection for him, in return for the love we know he bore to us."

"Our venerated patron and master was of a compassionate and sympathetic nature." "The suffering of others was a sorrow to him; his greatest happiness he found in doing good; his benevolence was inexhaustible, and numerous indeed are the examples amongst ourselves of that fact."

The farewell, forming the close of this discourse, bears strong testimony in itself, as well as from the point of view of the workpeople, to the inestimable qualities of one, who had not himself suffered impoverishment in the acquirement of riches, but who seems to have chosen to treat the latter merely as contributory to the acquirement of the inner wealth of a benevolent heart.

It is as follows:—

"Adieu, cher et regretté patron, votre vie n'a été qu'une longue suite de bienfaits. Nous conserverons éternellement le souvenir de tout ce que vous avez fait pour nous."—W. S.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*The Wearing Away of Metal Plates by the Action of Steam Jets.* J. Walter. Chem. Ind. 16, 170—171.

THE author was lead to the consideration of this subject by the behaviour of a steam-jacketed copper boiling pan. The copper pan was originally 8 mm. thick, and the steam entered the jacket at its lowest point. Being rather too small, the copper pan, after it had been at work for some years, was replaced by a rather deeper one, but one which in all other respects was exactly similar to the original pan. After the second pan had been in use for about a year, a hole was blown through the bottom, opposite the steam inlet to the jacket.

Believing that the mishap was due to the metal having been worked down too thin at this point, a third pan was made, slightly thicker—12 mm.—which was carefully measured all over, before putting into use.

To avoid a second accident the pan was tested from time to time, and after about 14 months' work it was found that the bottom had been reduced to the thickness of paper.

This time the author attributed the wear to the hydrochloric acid used for cleaning out the pan. He had previously noticed the "pitting" produced on iron plates by the action of steam jets, and, although he could not in this case trace the wear to the steam jet, he placed the steam inlet at the side, as a precaution. Some 11 months later he was convinced that the wear was due to the steam jet, as he found the pan again worn away; not at the bottom, but opposite the jet. The reason the original pan lasted so much longer, is due, the author thinks, to it being shallower than the others, and therefore not so near to the steam inlet and not subjected to such intense action. The author mentions a similar case that occurred with a lead-lined vessel which was heated by blowing in steam from pipes, perforated with rows of holes on each side, fastened to the bottom of the vessel by lead straps. From the stirring of the contents of the vessel one pipe got twisted, whereby the row of holes on one side pointed downwards. Very shortly the steam jets issuing from them pierced a row of holes through the lead bottom.

It is pointed out that the action of a steam jet is similar to that of a sand blast. In the former the abrading particles, instead of being sharp grains, are minute particles of water and rust, &c. from the pipes. Besides the purely mechanical abrasion there is also chemical action. The steam carries with it air, which oxidises the freshly-exposed surface, and the oxide film thus formed is more readily removed than the metal itself. The appearance of holes produced by the impinging of steam jets on to copper and cast-iron plates is described, and the author concludes by pointing out that once the cause of such wearing away is recognised, its prevention becomes easy.

This prevention can be effected by placing over the point of impact thick metal discs about 200 mm. diameter; by making the direction in which the steam enters parallel to, instead of across, the jacket space; or by placing a thimble, closed at the top and perforated at the sides, over the steam inlet.—R. B. P.

*The Internal Rusting of Boiler Shells.* Pfeifer. Papier Zeit. 18, 2617—2618 and 2654—2655. From Mitt. aus der Praxis des Dampf-kessel und Dampf-maschinen-Betriebes.

THIS report commences with an account of the physical and chemical phenomena which promote and cause the formation of rust upon iron. The internal rusting of boilers is dealt with under two headings, namely, when the boiler is in use, and when it is standing idle. The causes of rusting are first considered, the most important being the introduction of air with the feed water. By properly placing the feed pipe, namely, so that the feed water enters the boiler near the low-water level, and thus meets the hottest layers of water, the air is quickly expelled and passes out of the boiler with the steam, unless pockets exist

in which it can accumulate. Such pockets are sure to rust rapidly, and it is recommended that they should be covered internally with a protecting paint or filled up with cement, provided that they are not subjected to external heating. It is also recommended that the feeding should be completed before the withdrawal of steam ceases for the day, in order that the water left standing in the boiler over night may be as free from air as possible. An efficient circulation is also a means of preventing rusting, as it hinders the formation of air bubbles on the shell, which, if they remain clinging to it, cause rusting. The author is of the opinion that faulty construction is more often the cause of internal rusting than unfavourable conditions of working, and summarises the means of preventing rusting as follows:—

*First, whilst the boiler is working—*

1. Removing air from the feed water before it enters the boiler.
2. Removing air from the water whilst in the boiler, and preventing its accumulation in pockets, &c.
3. Addition of chemicals to the feed water.
4. Protective coatings applied to the inside of the shell.

*Second, whilst the boiler is standing idle—*

1. Removing all moisture from the boiler, (a) by blowing it off whilst hot, (b) by producing an air current through it, (c) by placing hygroscopic bodies inside.
2. Direct protection of the shells, (a) by painting with tar, varnish, &c., (b) by covering with protective paints, and such an alkaline coating as milk of lime.
3. Protecting the shells from varying temperatures by keeping the draught in the flues constant, and so as to prevent moisture alternately depositing and evaporating on the shell.
4. Protecting the shell by completely filling the boiler with water from which all air has been expelled.—R. B. P.

#### *The Removal of Boiler Scale by Means of Petroleum.* Papier Zeit. 18, 2916—2984.

AFTER some opinions stated *pro* and others *contra* with regard to the use of petroleum for removing boiler scale, the following is quoted as the opinion of Mr. Haage, the chief engineer of the Saxon Boiler Inspection Company:—that experiments made in 1873 showed that on account of the varying composition of boiler scale, the method was not generally applicable; in some cases it caused the scale to fall off, in others it merely loosened it, whilst in many cases it had no effect. It is also pointed out, in some correspondence given, that as the petroleum mixes with the steam the latter cannot be used for many industrial purposes, such as paper-making, when this method of removing boiler scale is adopted.—R. B. P.

#### *The Ether Motor of P. de Susini.* Freytag. Dingl. Polyt. J. 289, 104—107.

In this motor steam is replaced by sulphuric ether vapour, which is produced at relatively much lower temperatures, viz., 35° C. In the latest form of this motor the sulphuric ether vapour is generated by the direct action of steam, and is then used in the cylinders of a compound cylinder motor differing but little from an ordinary steam engine. The inventor claims a saving of 65 per cent. as compared with results with an ordinary condensing steam engine. Figs. 1 and 2 show the general arrangement of a plant on this system. A is an ordinary boiler, the steam from which passes along *a* to the cylinder jackets of the motor B, which are thereby raised to a rather higher temperature than that of the ether vapour entering the cylinders; from here it passes along the jacket *a'*, surrounding the motor inlet pipe *b'*, to the ether vapour generator C, any water condensed either in the pipes, cylinder jackets, or in E flows back to A, to be re-evaporated. The ether vapour is produced by the heat from the steam in E, and its pressure is regulated by the reducing valve R, which controls the pressure, and therefore the temperature, of the steam entering C; the ether vapour passes along the steam-jacketed pipe *b'* to the motor B, in which it performs work

successively in the two cylinders; it then passes into the condenser D. The liquid sulphuric ether formed here by condensation is forced by the pump E back into the generator C, where it is re-evaporated.

Fig. 1.

Fig. 2.

SUSINI'S ETHER MOTOR.

The difficulties formerly encountered in sulphuric ether motors consisted principally in leakage taking place at pipe and cylinder-cover joints, and at piston and valve rod stuffing boxes. These have been overcome by the design adopted, and by the exact work obtainable with modern machine tools.

As before stated, A is an ordinary steam boiler and B an engine differing but little from an ordinary inverted cylinder compound steam engine. Its cylinders are 229 mm. and 452 mm. diam. respectively and the stroke 300 mm. The construction of the ether vapour generator is shown in Fig. 3. It consists of two concentric cylinders. The inner

Fig. 3.

BOILER FOR SUSINI'S ETHER MOTOR.

one contains the sulphuric ether to be evaporated, and is traversed by a number of tubes passing through tube plates at each end. At the centre is a baffle plate through which the tubes pass, and which is perforated with holes between the tubes to allow the liquid in the cylinder to circulate. The tubes, of which there are 860, are 16 mm. diam. and 1 mm. thick. The steam, after it has passed round the cylinder jackets of the motor, enters at  $a^1 a^1$ , or steam direct from the boiler can be admitted, if desired, through the branch II, Fig. 1. Any water condensed, passes out through  $c$  back to the boiler;  $v$  serves for filling in sulphuric ether and  $m$  and  $n$  are connected respectively to pressure and vacuum gauges. Two safety-valves, one for the outer and the other for the inner cylinder, are fitted, and blow off into the pipe  $f^1$  (Fig. 1) leading to the outer air. The ether vapour produced passes to the motor through  $b^1$ . The condenser D is very similar in construction to C. The vapour passes into the inner cylinder, and cold water entering at  $x$ , Fig. 2, passes through the tubes, of which there are 1,264 of 11 mm. diam. and 0.5 mm. thick, and flows back through the space between the inner and outer cylinders to the exit pipe  $y$ , Fig. 2. D has also two safety-valves discharging into the pipe  $f^1$ .

Fig. 4 shows the method of packing the piston and valve rods. Each stuffing box is surrounded by a casing

Fig. 4.

STUFFING BOX FOR SUSINI'S ETHER MOTOR.

filled with glycerin, which passes through suitable apertures into a small piston in the stuffing box. The glycerin prevents the escape of vapour and at the same time lubricates the rod. Any vapour that may find its way into the stuffing box passes up into a small reservoir situated on top, and passes out through the upper pipe to the condenser D, Fig. 1. This reservoir is partially filled with glycerin, which passes into the casing round the stuffing box through the dotted pipe. The ether vapour on its way to D passes through F, where any glycerin it may carry over is arrested. F consists of a cylinder containing a series of concentric baffles. The plant is designed to work with live steam, but will work equally well with exhaust steam if automatic valves for dealing with water of condensation are fitted. The initial pressure of the ether vapour is 25 atmospheres, and the steam pressure 8 to 10 atmospheres. With the boilers evaporating 420 kilos. of water per hour the motor gave 50 actual horse power.—R. B. P.

*A Recuperative Gas Furnace.* C. Bigot. Monit. Scient. 1893, 7, 519.

See under XXIII., page 174.

*Filter for Diffusion Juice.* Bouvier. Zeits. Zuckerind. Böhmen, 1893, 18, 64.

*Brown Paper from Wood.* Papier Zeit. 18, 2653.

See under XIX., page 170.

#### PATENTS.

*A Method of Lining Spigot and Socket, Flange or Snug Pipes with Enamel, Glass, Composition, or other Material.* F. Herbert, Birtley, near Newcastle. Eng. Pat. 22,682, December 13, 1892.

See under VIII., page 154.

*An Improved Furnace Pan and Concentrator for the Boiling of Fish Livers and the like.* C. B. Lotherington and I. Spencer, Hull. Eng. Pat. 23,542, December 21, 1892.

See under XII., page 162.

*Improvements in Filters.* E. Delhotel and E. Moride, Paris. Eng. Pat. 23,830, December 24, 1892.

In ordinary sand filters for the purification of water the upper surface of the sand soon becomes coated with the impurities contained in the water, whereby the action of the filter is considerably impeded.

In order to avoid this, the inventors give to the incoming water a gyratory action by making the inner end of the inlet pipe annular, and providing it with a number of angular branches, thus causing the water to issue tangentially therefrom, and to being kept in constant rotation above the surface of the sand.

Through the centre of the casing passes a vertical pipe, having an outlet below closed with a tap, the upper end reaching nearly under the cover of the casing and finishing with a bell-shaped mouthpiece.

When the rotary mass of water above the bed of sand has taken up a sufficient amount of impurities, the tap of the vertical outlet is opened and the impure water driven out through the vertical pipe, either by the pressure of the unfiltered water, or by the current of filtered water reversed for the purpose.—B.

*Improvements in the Heating of Surfaces for the Drying, Heating, or other Treatment of Paints, Oxides, or other Matters by the Aid of Electricity, and in the Means or Apparatus employed therein.* R. E. B. Crompton and H. J. Dowsing, London. Eng. Pat. 259, January 5, 1893.

See under II., page 138.

*Improvements in Apparatus and Appliances for Obtaining more perfect Combustion of Fuel in the Furnaces of Steam Generators or other Furnaces.* S. Taylor, Sheffield. Eng. Pat. 587, January 11, 1893.

See under II., page 139.

*Improvements in or applicable to Brine-evaporating Pans.* J. Parks, Northwich. Eng. Pat. 2400, February 3, 1893.

See under VII., page 151.

*Improvements in Apparatus used in the Concentration of Sulphuric Acid.* I. Levinstein, Manchester. Eng. Pat. 2476, February 4, 1893.

See under VII., page 152.

*Improvements in Thermostats.* A. Shields, Glasgow. Eng. Pat. 3057, February 11, 1893.

THE invention has reference to that class of thermostats in which the expansion and contraction of a sensitive fluid such as mercury, spirit, or the like, operate a diaphragm connected with the controlling apparatus. The apparatus consists of a chamber divided into two parts by a flexible diaphragm, the upper part being connected by a rod or link to a valve for regulating the supply of heating or cooling fluid; and the lower part communicating by means of a branched pipe with a reservoir of the sensitive fluid. The expansion of the fluid moves the flexible diaphragm and connecting link, thereby operating the controlling valve, while a spring brings back the diaphragm when contraction takes place. To prevent great expansion from bursting the apparatus, a safety diaphragm chamber is provided with its lower part communicating with the sensitive fluid and the upper face of the diaphragm pressed down by a powerful spring or by gas under pressure. When the expansion in the regulating chamber has reached the maximum amount, the safety diaphragm will begin to lift against the pressure above it, and thus all danger of bursting the apparatus will be avoided. The reservoir and the safety and regulating chambers are connected up by piping and provided with suitable gas cocks and valves; they are mounted on one casting.—E. G. C.

*A Process and Apparatus for Converting Non-Gaseous Hydrocarbons and Materials Containing them into Combustible Gas.* F. Siemens, London. Eng. Pat. 4022, February 23, 1893.

See under II., page 139.

*Improvements in or relating to Apparatus for Galvanising Sheet Metal.* J. V. Lagnesse, Grevegnée, Belgium. Eng. Pat. 4298, February 27, 1893.

See under X., page 158.

*Improvements in Gas Producers.* E. J. Duff, Glasgow. Eng. Pat. 7467, April 12, 1893.

See under II., page 140.

*An Improved Method of and Apparatus for Filtering.* J. P. Prat, Bordeaux, France. Eng. Pat. 7644, April 14, 1893.

THIS refers principally to filters in which conical filtering bags are employed, which in this case are stretched over skeleton frames made in the shape of double cones, one central cone surrounded by an annular cone joined at their bases. The small end of the bag is tied to the small end of the central cone, the bag then pressed into the annular valley between the two cones, and the larger end covering the outer surface of the larger cone, being finally tied at the largest diameter. The full length of the bag is thus made use of in an apparatus the height of which is about one-third only of the length of the bag.—B.

*Improvements in the Method of and Apparatus for Manufacturing Cyanides, Ammonia, and Fuel Gas.* A. J. Boulton, London. From E. Cowen, New York, U.S.A. Eng. Pat. 13,069, July 4, 1893.

See under II., page 140.

*Improvements in the Manufacture of Ammonia, Sodium Hydroxide, and Chlorine, and in Apparatus therefor.* C. Kellner, Vienna. Eng. Pat. 13,722, July 14, 1893.

See under VII., page 152.

*A Method of and Apparatus for Effecting the Absorption of Carbonic Acid.* A. Müller, Nieder Schonweide, near Berlin. Eng. Pat. 13,928, July 18, 1893.

See under VII., page 152.

*Improvements in Apparatus Employed in the Manufacture of White Lead.* J. V. Walton, Darlington. Eng. Pats. 3116, February 11, 1893, and 16,703, September 5, 1893.

See under XI., page 163.

*Improvements in or relating to the Treatment of Fish and Fish Offal and in Apparatus therefor.* J. C. W. Stanley, London. Eng. Pat. 17,205, September 13, 1893.

See under XV., page 165.

*Improvements in Apparatus for Illuminating and Heating by Means of Petroleum.* E. de Pass, London. From J. Leemana, St. Gallen, Switzerland. Eng. Pat. 18,660, October 5, 1893.

See under II., page 141.

*Improvements in Chamber Kilns.* F. H. Jung, Salisbury. Eng. Pat. 18,829, October 7, 1893.

See under VIII., page 154.

*Improvements in Filters.* J. N. S. Williams, Glasgow. From L. Spalding, Kauai, Hawaiian Islands. Eng. Pat. 20,006, October 24, 1893.

IN carrying out this invention a tank is employed through which passes a horizontal pipe at a convenient height from the floor. From both sides of this pipe branch off a number of smaller pipes closed at their outer ends, but perforated throughout their length. Suspended from each branch pipe is a frame of meshed wire, covered with a woven cloth bag, which also entirely encloses the branch pipe. The liquid to be filtered is maintained in the tank at a level above the pipes, from which it is discharged after having passed through the filtering bags.—B.

*An Improved Apparatus for Sterilising or Disinfecting Liquids.* J. H. W. Ortmann and C. W. C. Herbst, Hamburg, Germany. Eng. Pat. 19,760, December 23, 1893.

THE apparatus is intended for heating uniformly, liquids contained in bottles (Pasteur's method). The bottles are placed on a plate resting on blocks a short distance above the bottom of the bath. This plate has a series of perforations close to the edge, and there is a space of about 10 mm. between the outer edge and the sides of the bath. The plate has also a large central opening connected with a discharge pipe, which passes through the bottom of the bath. In the bottom of the bath there are two inlet pipes, about half way between the centre and the ends.

The bath is first filled with cold water. Hot water is then admitted through the two pipes into the space between the two bottoms. The heated water rises at the edge of the false bottom, and through the perforations, whilst the displaced colder water is discharged through the central pipe. This pipe has a special opening below the false bottom for the discharge of any cold water between the two bottoms.

The water becomes thus slowly but uniformly heated, and the desired temperature may be maintained as long as required by slow additional heating.—N. H. J. M.

## II.—FUEL, GAS, AND LIGHT.

*The Amount of Cyanogen in Gas-purifying Material and its Influence on Regeneration.* Dr. Burschall. J. für Gasbeleuchtung, 36, 7—10.

THE author points out that the Prussian blue formed during the purification of coal gas can be recovered almost without additional cost, and should form a source of extra profit.

He describes at length his own experiments on the subject, and summarises them as follows:—

The presence of ammonia during the purification causes a twofold formation of sulphocyanide, the amount of which, though it cannot be diminished in the purifier, nor its formation during the regenerating process entirely avoided, may in the latter process be diminished, first, by avoiding excessive heating of the mass; secondly, by getting rid of the ammonia as quickly as possible; both of these conditions are promoted by sifting the material as soon as possible after its removal from the purifier, when it contains the greatest amount of moisture, and also by spreading it out in as even a layer as possible, for regeneration. It must not be overlooked that old purifying material does not fix as much water as fresh material, and that the water formed during the absorption of sulphuretted hydrogen may cause disturbances. By rapid sifting a speedy regeneration takes place, and if a thorough airing does not at the same time ensue, the temperature rises and aids the formation of the sulphocyanide. The formation of Prussian blue, in spite of the ease with which the sulphocyanide is formed from cyanogen in the presence of ammonia and hydrogen sulphide, is explained by the fact that a not inconsiderable quantity of cyanogen escapes absorption in the first purifier, where most of the ammonia and hydrogen sulphide are caught, and consequently a fairly large quantity of cyanogen passes to those parts of the purifying plant where there is no hydrogen sulphide and only traces of ammonia present. Here the fresh purifying material permits a reaction to take place between the cyanogen and the oxide of iron, the compounds resulting from which cannot be transformed into the sulphocyanide at ordinary temperatures by ammonia and hydrogen sulphide, but require higher temperatures, such as occur during the further process of regeneration. It is these portions of the cyanogen which can be recovered as useful products by proper subsequent treatment of the purifying material, even in works where the gas is insufficiently washed.—R. B. P.

*Oxy-Oil Gas (Tatham's Process) and its Use for Purposes of Enrichment.* L. T. Thorne. Read before the Southern District Association of Gas Managers, November 23rd, 1894.

SOME time ago the author described (Incorp. Gas Inst. Trans. 1890, 143) the results of preliminary experiments to test the accuracy of the claims put forward by the patentee of this process, and expressed a favourable opinion thereon. In the present paper he describes further experiments on oxy-oil gas and gives the practical results obtained with it at Huddersfield, where it is now manufactured and used for enriching the town gas. The Huddersfield plant is designed to give an output of 200,000 cub. ft. of oxy-oil gas per day, but when the author's experiments were made there a portion only of the plant, producing about 40,000 ft. per day, was completed.

The essence of the Tatham process lies in the addition to heavy hydrocarbon gases, from whatever source obtained, of considerable quantities of free oxygen, this addition being preferably effected soon after the gases leave the retorts and whilst they are still hot. At present various low-priced petroleum and shale oils, which can be obtained in bulk in England at 3l. per ton, have been employed for making the oil gas. When oxygen is added to a heavy oil gas whilst the latter is still hot the illuminating power of the gas is raised. The maximum increase is obtained when from 12 to 18 per cent. of oxygen (according to the quality of the oil gas) has been added. Further addition of oxygen up to about 16 to 24 per cent. causes no further

change in the actual illuminating power, but renders the flame stiffer, whiter, and brighter to the eye, reduces the size of the dark zone, and improves the general shape and appearance of the flame. Still further addition of oxygen gradually reduces the illuminating power of the flame. The increase of illuminating power with very heavy oil gas is 25 per cent. or even more, with lighter oil gas rather less. As a rule the most suitable percentage of oxygen in the oxy-oil gas is about 20 per cent. if the oxy-oil gas is to be burned *per se*, about 15 per cent. if it is to be used for the enrichment of coal gas, &c. An oxy-oil gas showing an illuminating power of about 100 candles can be made, but taking into account both quantity and quality the most economical working in practice will probably be to produce an 80-candle gas, of which at least 25,000 cub. ft. would be obtainable per ton of oil used. Experiments have shown that oxy-oil gas is exceedingly stable. For instance, 500 ft. of oxy-oil gas kept in a 3,000-ft. holder for a week during varying frost and wet and stormy weather in November only lost 5.5 per cent. in illuminating power. When used as an enricher it is found that oxy-oil gas actually increases the stability of poor coal gas. A number of tests were made in which oxy-oil gas was added to unenriched coal gas and the mixtures then subjected to severe cold for some days. The mean of the results showed that, under like conditions, the unenriched coal gas lost 1.35 candles, that containing 5 per cent. of oxy-oil gas lost 0.95 candle, and that with 10 per cent. oxy-oil gas only 0.5 candle.

Experiments were made at Huddersfield extending over some time to determine the enriching power of the oxy-oil gas. The readings were all taken with a 2-candle Methven screen on a 60-in. photometer, the gas being in all cases burned from a standard argand burner. The following results were obtained:—

Gas.	Average Candle Power.	Number of Readings Taken.	Percentage of Oxy-Oil Gas in Tested Gas.	Gain of Illuminating Power Per Cent. of Oxy-Oil Gas.
Unenriched	14.42	600	..	..
Enriched...	17.05	480	2.96	0.89
" ...	18.07	120	4.51	0.81

thus showing a gain of over four candles for a use of 5 per cent. of the enriching gas. For comparison, oil gas was made under identically similar conditions (except of course the addition of oxygen), and enrichment tests made with this. The average of 150 tests gave an increase of 1.87 candles for 3.05 of oil gas or 3.05 candles for 5 per cent. enricher. The gas enriched with oxy-oil gas has a whiter and brighter appearance and a prettier-shaped flame than that enriched with cannel or with oil gas. The author estimates the cost of enrichment of coal gas by oxy-oil gas, at the present price of petroleum, at about one-third of a penny per candle per thousand cubic feet.—L. T. T.

### PATENTS.

*Improvements in the Heating of Surfaces for the Drying, Heating, or other Treatment of Paints, Oxides, or other Matters by the Aid of Electricity, and in the Means or Apparatus employed therein.* R. E. B. Crompton and H. J. Dowsing, London. Eng. Pat. 259, January 5, 1893.

THESE improvements are intended for the utilisation of electric currents for heating surfaces for drying or heating or roasting different materials in a cleanly manner, free from products of combustion, or which require to be heated in the presence of certain gases, and for this purpose electric conductors are embedded in refractory insulating material in the manner described in Eng. Pat. 17,091, 1892, which is preferred for the roasting of ores. Inclined drying shelves are shown arranged in a vertical chamber

or furnace, so that the material to be heated, fed into the chamber by an archimedean screw at the top, falls from one shelf to another into a collecting chamber at the bottom. The temperature of these shelves may be separately varied by resistances. The wires for high temperatures should be of steel, or alloys of nickel and steel, known as nickeline, embedded in ganister or silicious sand.—J. C. R.

*Improvements in Apparatus and Appliances for Obtaining more Perfect Combustion of Fuel in the Furnaces of Steam Generators or other Furnaces.* S. Taylor, Sheffield. Eng. Pat. 587, January 11, 1893.

This invention has for its object the introduction of air through a hollow fire bridge provided with suitable air in- and outlets. A number of metal projections, the object of which is to conduct heat to the air passing through the fire bridge, project horizontally from the front plate of the fire bridge inside. There is a second solid fire bridge behind the front one, which becomes highly heated by the fire and on which the heated air from the first or hollow bridge impinges, and causes a more perfect combustion. The air inlet to the hollow bridge can be opened or closed by two sliding plates, one of which is for regulating the amount of air passing through, and the other for automatically opening and closing it. The latter is controlled by a system of levers and rods in such a manner that when the fire door is opened for stoking, the air inlet is opened and admits air to the bridge; it remains open for a sufficient time after the door is closed to obtain a perfect combustion, the time being regulated by a cataraet cylinder attached to the mechanism.—R. B. P.

*A New and Improved Method for Saponifying or Mixing Tars, Oils, Hydrocarbons, and similar Materials, and for using the same for Heating, Lighting, and other Purposes.* C. A. Sahlstrom and E. Parr, both of London. Eng. Pat. 2155, January 31, 1893.

In one vessel the oil or other material is heated from 70° to 110° F. by passing through it a current of hot air or steam from a coil situated at the lower part of the vessel, and perforated with a series of fine holes. In another vessel water containing from  $\frac{1}{2}$  per cent. to 3 per cent. of alkali is heated to the same temperature. This solution is then run in a fine stream into the oil in the first vessel, which is continuously stirred during the mixing and for some 5 to 15 minutes afterwards. In this way the oil or other material can be made to take up as much as 150 per cent. of water. The resulting mixture can be used for lighting and heating alone, or it can be made into solid fuel by the admixture of ground peat, spent tan, sawdust, coal dust, or similar materials, and subsequently pressed into blocks.—R. B. P.

*Improved Apparatus for Vaporising and Burning Mineral Oil.* B. Grosche, London. Eng. Pat. 2901, February 9, 1893.

This invention has for its object the production of a cheap and efficient burner for mineral oil. In it the oil first passes through a "trap" filter and is then vaporised in a specially-shaped generator, whence the vapour passes upwards and strikes a "spreader" placed over the mouth of the burner, where it burns.—R. B. P.

*A Process and Apparatus for Converting Non-gaseous Hydrocarbons and Materials containing them into Combustible Gas.* F. Siemens, London. Eng. Pat. 4022, February 23, 1893.

This invention relates to the production of combustible gas from hydrocarbons such as petroleum, paraffin, naphtha, fats, tars, resins, wax, naphthalene, and the like, by igniting the surface of the hydrocarbon in a suitable chamber, and, after ignition, limiting the amount of air admitted. The heat

of combustion converts the hydrocarbon into combustible gas, which, together with the products of combustion, are led away for subsequent use.

Fig. 1 shows a vertical section through a suitable form of apparatus, and Fig. 2 a horizontal section on the line X-X.

Fig. 1.

Fig. 2.

A is an annular reservoir supplying the liquid hydrocarbon, or the hydrocarbon liquefied by heat, to the central combustion chamber C through the pipe B. Through the cover of C are pierced a number of small holes D, admitting air to the surface of the hydrocarbon. An elbow pipe F, the lower end of which is covered by a perforated plate, and the upper end by a hinged door G, serves, by opening or closing G, to admit a further quantity, greater or less as required, of air to the chamber C. A lighted taper is introduced through H to ignite the hydrocarbon. Combustible gas is then produced, which ascends through K to a gas-holder.—R. B. P.

*An Improved Method of and Apparatus for Burning Hydrocarbons for Lighting and Heating Purposes.* F. B. Hill and R. D. Brett, both of London. Eng. Pat. 4211, February 25, 1893.

The object of this invention is to facilitate the combustion of heavy hydrocarbons, such as crude petroleum or tar. This is effected by using a jet of vapour of a lighter hydrocarbon, such as paraffin, in place of the usual jet of air, or of air and steam mixed. The figure shows the construction of the lamp: a is the receptacle for the heavy oil, the level of which is kept constant by a small cistern, fitted with a ball-cock, placed between the reservoir and a; b is the jet, and is in connection with the vaporising coil d. The latter receives the supply of light hydrocarbon through d<sup>2</sup>; e is a hood, perforated round its lower edge with air-supply holes e<sup>1</sup>; e is the outer casing, which is supported on lugs a<sup>2</sup> in such a manner as to admit air to the space between e and c. The

reservoir for feeding the lamp has two compartments, a large one for the heavy, and a smaller one for the light hydrocarbon. A pipe passes down to near the bottom of each, the one leading to the intermediate cistern for controlling the level of the heavy hydrocarbon in *a*, and the other supplying *d* with light hydrocarbon. The reservoir

is fitted with an air-pump for producing a pressure in its upper part to force up both the heavy and light hydrocarbon. In operating the lamp, the heavy hydrocarbon in *a* is ignited. The air entering through *c* is sufficient to produce a partial combustion, whereby an inflammable gas is produced, which mixes with the vapour of the light hydrocarbon issuing from *b*, and is carried upwards with it through the top of *c*; it here meets the air passing between the casing *e* and the hood *c*, and burns with an intense flame.—R. B. P.

*Improvements in Gas Producers.* E. J. Duff, Glasgow.  
Eng. Pat. 7467, April 12, 1893.

In order to reduce the cost of construction, the producer is made rectangular in form. It is built up of plane, flanged, cast-iron plates, and lined with fire-brick.

The air for combustion enters from a lower casing through perforated cast-iron plates, which slope upwards from the sides and meet at a ridge along the centre. Air is injected and fuel fed in in the usual manner. The ashes descend on each side of the ridge and fall through suitable openings along each side into a trough, which is partially filled with water, thus sealing the lower part of the producer.

—R. B. P.

*An Improved Fuel.* D. W. Nightingale and S. G. Wicking, both of London. Eng. Pat. 8040, April 20, 1893.

THIS is a mixture of 1 part gas tar, 4 parts petroleum, and 20 parts pulped waste material. The latter may be of any kind, such as old fibrous or textile material. The ingredients are incorporated and then pressed into blocks.

—R. B. P.

*Improvements in the Method of and Apparatus for Manufacturing Cyanides, Ammonia, and Fuel Gas.* A. J. Boulton, London. From E. Cowen, New York, U.S.A.  
Eng. Pat. 13,069, July 4, 1893.

THIS invention has for its object the rapid and economical production of compounds of nitrogen suitable for agricultural and industrial arts, and simultaneously the production of fuel gas.

Fig. 1 shows the general arrangement of the plant, in which A is a steam generator, B a gas producer, and C an apparatus for the production of cyanides, &c. By means of an injector or other similar appliance, *x*, a mixture of

steam from A, and air is passed through a mass of incandescent fuel in B. In B, carbon mon- and di-oxide are formed, whilst hydrogen is freed, the resulting gas consisting of a mixture of these bodies with a large volume of nitrogen

Fig. 1.

in a condition suitable for the formation of cyanides. The construction of C is shown in Fig. 2. It consists of a stack of refractory material, at the upper end of which is the feed

Fig. 2.

mechanism. M is a vertical retort, of refractory material also, which communicates with a tank L and a washer K. P

and  $P^1$  (Figs. 2 and 3) are superheaters. The arrangement of the various ports, passages, fire, &c. is shown in the

Fig. 3.

figures. Assuming that the apparatus, including one of the superheaters, has been brought to a sufficiently high temperature by the fire D, communication is established so that gases from B (Fig. 1) flow through the hot superheater and  $S^1$  into the feed opening, where they meet the material falling from the feed apparatus and pass down therewith through

Fig. 4.

the retort M. Simultaneously, a suitable volume of hydrocarbon gas or vapour, or a mixture of both, is introduced through J, which mixes with the gases from B. The material referred to above, which is fed in through the feeder at the top, consists of a suitable volume of alkali or alkaline earth. In passing through M, the gases being subjected to a high

Fig. 5.

temperature are split up and new compounds are formed. The various reactions going on are described, which are said to result in the formation of cyanogen and its salts, ammonia, and fuel gas which passes out over the water in the tank L, up through the washer K, and out through the pipe O. Various modifications in working, for varying the relative proportions of the bodies produced, are described.—R. B. P.

*Improvements in Apparatus for Illuminating and Heating by means of Petroleum.* E. de Pass, London. From J. Leemann, St. Gallen, Switzerland. Eng. Pat. 18,660, October 5, 1893.

This invention relates to improvements in the apparatus described in Eng. Pat. 13,681, August 30, 1890. The improvements aim at obtaining a more perfect combustion. The burner consists of two flat zig-zag passages formed of parallel tubes screwed into suitable top and bottom fittings; these are placed opposite each other at a small angle, and surrounded on four sides by metal plates, thus forming a hollow wedge-shaped box open at the top and bottom. Oil is fed into each of the zig-zag passages and is vaporised therein. The vapour passes into the wedge-shaped box at its lower, or wider end, and issues at the upper narrower end, where it burns, heating the burner and vaporising the oil. Air is pumped into the oil reservoir so that it bubbles up through the oil. The lamp is started in the usual way.—R. B. P.

*Improvements in Apparatus for Carburettling or Enriching Gas or Air.* A. Love, Barking, Essex, and D. Weston, London. Eng. Pat. 20,860, November 17, 1893.

The method of enriching gas adopted in this invention is to inject a spray of the enriching medium into a chamber through which the gas to be treated is passing, the latter at the same time being thoroughly stirred by means of paddles revolving in the said chamber. Briefly the apparatus consists of three parts: (a) a chamber for receiving the enriching medium; (b) a plunger pump for producing the spray; and (c) the enriching chamber for treating the gas in.

These three parts are shown superposed: (a) is at the top, and consists of a simple chamber into which the enriching medium is fed by forcing compressed air into the top of the air-tight casks in which it is stored. Any vapour given off from the enriching medium collects in the upper part of the chamber (a), and passes thence to the gas main, where it mixes with and helps to enrich the gas. From (a) the enriching medium passes through a "sight-feed" tube, fitted with a regulating cock to the suction pipe of the plunger pump (b). The suction pipe is so placed that the plunger shuts it off from the pump barrel except just at the end of its out stroke. In this latter position the enriching medium flows into the pump. The plunger then descends, cuts off the suction inlet, and forces out the enriching medium that has entered the pump, driving it through a perforated diaphragm, in the form of a spray, into the lower chamber (c). This is a cylindrical casing fitted with removable end covers, which carry by means of glands a rotating shaft, to which are attached the paddles. The latter consist of a light framework covered with wire gauze. The chamber (c) is arranged as a by-pass to the gas main in such a manner that either the whole or only a part of the gas passing through the main can be sent through it. The gas in (c), by the stirring action of the rotating paddles, is brought in intimate contact with the enriching medium injected as a spray, and also with a film of it that forms on the paddles, and thus becomes thoroughly enriched or carburetted.—R. B. P.

*Improvements in the Manufacture of Incandescent Bodies for Incandescent Gas Lighting.* R. Langhans, Berlin, Germany. Eng. Pat. 22,396, November 22, 1893.

THE object of this invention is to render the oxides employed as a skeleton for incandescent gas lighting more durable in regard to their fragility, and consists, mainly, in employing, instead of a cotton fabric, a tissue or plaiting of very fine platinum wires, which are covered or coated by electrolysis, with the oxyhydrates, carbonates, tartrates, or oxalates, by connecting the platinum tissue with the negative pole of a source of electricity (corresponding to a cathode), immersed in a saline solution, or a mixture of saline solutions of the suitable earthy metals, until a sufficiently thick layer of the oxyhydrates and other insoluble compounds is deposited upon the metallic foundation or base.

Advantages are said to be derived from adding ammoniacal, rather than sodium or potassium, salts to the electrolyte, hydrates of the latter being inseparable from the precipitates. These precipitates are slowly dried, and then heated until nothing remains on the platinum wires but pure oxides, either alone or in combination.

It is also proposed to wrap cotton wool, &c. on the platinum wire, or to wrap platinum on a core of yarn, in various ways, and then treat electrolytically; and other methods and materials are mentioned for obtaining metallic and non-metallic foundations, as aluminates and certain silicates, in conjunction with conducting carbonised organic textile fibres; and aluminium covered electrolytically with oxides, and then itself converted into a hydrate by immersion for three or four days in a strong solution of peroxide of hydrogen, which is said to produce a fixed hydrate without deformation.—J. C. R.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*The Alkali Test for Kerosene Naphtha Products, &c.* K. Lissenko and A. Stepanow. *Dingl. Polyt. J.* **290**, 139.

### IV.—COLOURING MATTERS AND DYES.

*The Colouring Matter of Cochineal.* W. v. Miller and G. Rohde. *Ber.* **26**, 2647.

THE first important result regarding the constitution of the colouring matter of cochineal was obtained by Warren de la Rue, who discovered nitro-cochineic acid amongst the products of the oxidation of carminic acid with nitric acid. Liebermann and Dorp showed this acid to be trinitrocresotinic acid, the constitution of which, according to Kostanecki and Niementowski, is:—

The observation of Hlasiwetz and Grabowski that carminic acid is a glucoside capable of decomposition into glucose and carmine red, has been shown by various observers to be erroneous. Of the greatest interest was the discovery by Will and Leymann of two bromine derivatives of carmine red, which on further treatment yielded a methyl-dibrom-hydroxyphthalic acid—

The formation of this acid is due, as the authors of the paper show, to the decomposition of a bromine derivative (a) of carmine red of the formula—

by means of a solution of sodium carbonate. The other (b) of the two above-mentioned bromine derivatives of carmine red appears to stand intermediate between carmine red and the  $\alpha$ -derivative referred to, as the latter is easily converted into the former by oxidation with bromine in a solution of sodium carbonate. This fact strongly points out the naphthoquinone nature of  $\beta$ -bromocarmine, and indeed it was found that  $\beta$ -bromocarmine, on reduction with zinc dust in an alkaline solution, yields a hydroquinone, and from this fact one may infer that  $\beta$ -bromocarmine is a derivative of an  $\alpha$ -naphthoquinone and possesses the formula—

The conclusion is arrived at that carminic acid, which is identical with carmine red, is itself a derivative of methyl-dihydroxy- $\alpha$ -naphthoquinone of the formula—

With regard to the future synthesis of carminic acid, experiments to produce the dihydroxynaphthoquinones—

would be of very great interest.—C. O. W.

*Constitution of Hydrocyanorosaniline and Fuchsin.* E. Fischer and W. L. Jennings. *Ber.* 1893, **26**, 2221—2225.

THE hydrocyanorosaniline prepared by E. and O. Fischer (*Annalen*, **194**, 275) has the constitution  $\text{CN} \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2$ . Rosenstiehl believes that the coloured salts of *p*-rosaniline have an analogous constitution, from which it might be supposed that the compounds would bear a great resemblance to one another, instead of which they are in every way dissimilar. Rosenstiehl's formula does not explain the relation of *p*-fuchsin to rosolic acid, which relation is clearly shown by Nietzki's quinonoid formulae, thus:—

The analogy which exists between quinone compounds and the rosaniline dyes was pointed out by Graebe and Caro (*Annalen*, **179**, 184). Rosenstiehl's chief objection to the older formulae for the salts of *p*-rosaniline is that

these formulæ do not explain the combination of three additional molecules of acid; this, however, finds its analogy in the combination of quinone with hydrogen chloride. The constitution of the salts of rosaniline containing 4 molecules of acid is not, however, definitely settled.

The authors have effected the conversion of pararosaniline into triphenylcarbinol by employing the Sandmeyer-Gattermann diazo method; the views of E. and O. Fischer (*loc. cit.*) as to the relation of these compounds are therefore confirmed.—A. R. L.

*Pararosaniline and its Salts.* A. Miolati. Ber. 1893, 26, 1788—1790.

THE change which takes place when *p*-rosaniline  $\text{OH} \cdot \text{C}(\text{C}_6\text{H}_4 \cdot \text{NH}_2)_3$  is converted into its coloured salts is at present a moot point. E and O. Fischer regarded the constitution of *p*-fuchsin as—

whilst Nietzki in 1889 (Chem. d. organ. Farbstoffe, S. 87) assigned to it the formula of a substituted quinone-imide derivative—

and Rosenstiehl and von Richter suggest that it may be formed by simply substituting chlorine for hydroxyl in *p*-rosaniline, which leads to the formula  $\text{Cl} \cdot \text{C}(\text{C}_6\text{H}_4 \cdot \text{NH}_2)_3$ . Now if the latter hypothesis be correct, *p*-fuchsin, like other analogous compounds, must be a non-electrolyte, whereas by either of the first two formulæ, which represent it as the hydrochloride of a base, it must conduct electricity.

The author has proved experimentally that the solution of the salt does conduct electricity, its molecular conductivity being about 46.5, or about half that of quinaldine (J. Walker, Zeit. physik. Chem. 4, 333), *p*-rosaniline is accordingly a very strong base. *p*-Fuchsin must therefore undergo electrolytic dissociation in aqueous solution, and cannot have the constitution assigned to it by Rosenstiehl and von Richter.—A. R. L.

*The Formamides of Alizarin.* M. Prud'homme and C. Rabaut. Bull. Soc. Ind. Mulhouse, 1893, 223—224.

By the action of formic acid the amidoalizarins yield formamides.

*β-Amidoalizarin.*—One part of *β*-amidoalizarin, dried and reduced to fine powder, and 10 parts of formic acid (20° B.), are heated together for 7—8 hours. The product of the reaction diluted with water, is thrown on to a filter and washed with distilled water. Caustic soda or potash dissolve it to a bluish-violet, ammonia to a red-violet solution. These solutions do not deposit lakes like those of amidoalizarin. The formamide in the dry state has a yellow colour, whereas *β*-amidoalizarin is brick-red. Treated with concentrated sulphuric acid at 150° it yields *β*-amidoalizarin with liberation of  $\text{CO}_2$ . Heated on a water-bath with glycerol and sulphuric acid it is transformed into alizarin blue.

This product is the dihydroxyanthraquinone formamide of the formula  $[\text{OH}:\text{OH}:\text{N}:\text{CHO}=1:2:3]$ . It is slightly soluble in water. With alumina it yields an orange, with chromium and iron mordants browns are obtained. If calcium acetate be present in the dye-bath, alumina gives brownish-red; chromium, brown; iron, black or violet shades.

*α-Amidoalizarin.*—The author has obtained the dihydroxyanthraquinone formamide  $[\text{OH}:\text{OH}:\text{N}:\text{CHO}=1:2:4]$ . The colour of its alkaline solutions differs little from those of *α*-amidoalizarin. In the dry state this product is yellowish-brown. Concentrated sulphuric acid transforms it first into *α*-amidoalizarin, then into purpurin. With glycerol and sulphuric acid it yields the corresponding alizarin blue. It

is slightly soluble in water. The shades given with the various mordants are very similar to those yielded by alizarin. The addition of calcium acetate has little effect.

—R. B. B.

*A New Direct Grey.* Report by T. Rammann on a Paper by M. Petzold. Bull. Soc. Ind. Mulhouse, 1893, 221—222.

A MIXTURE, in molecular proportions, of aniline hydrochloride and hydrochloride of nitrosodimethylaniline is slowly heated to 60°. The yellow mass becomes in turn darker yellow, yellowish-green, and black, finally violet-blue. When this point is reached all the nitrosodimethylaniline will have entered into combination. The reaction is complete when a small portion of the product placed on filter paper and moistened with boiling water no longer gives a yellow ring. The colouring matter is then precipitated with common salt and zinc chloride. After being dried and ground it appears as a black powder, dissolving easily in cold water to a violet-blue solution. The author believes that this colouring matter may be considered as the hydrochloride (or double zinc salt) of an indamine, the base having the constitution—

This formula is somewhat doubtful, considering the instability of the indamines.

The product is a basic grey, dyeing cotton, wool, and silk directly. It can be applied to either fibre as a steam colour. It is dyed on cotton either direct or with tannin mordant. When applied with tannin and antimony salts it resists the action of sulphuric acid, chlorine, soap, and light.

Generally speaking, it behaves like other basic greys, *e.g.*, nigrosine, nigramine, and methylene grey.—R. B. B.

*The Oxidation of Paratoluidine.* A. G. Green. Proc. Chem. Soc. 1893 [129], 237—238.

THE red crystalline substance obtained by Barsilowsky in 1873 by oxidising paratoluidine with potassium ferrocyanide has been variously considered as a polymeric paratoluene, as a tritoluylenediamine, and a complex amidoazo compound. The author has re-examined this remarkable substance. He arrives at the conclusion that the substance is a diparatolylimide represented by the formula—

derived from amidoaliquinone. On reduction, it takes up two atoms of hydrogen, affording a stable, colourless, leuco base. This latter is readily re-oxidised to the original substance, has very slight basic properties, and is not decomposed by acids or further reduced by boiling with stannous chloride. The leuco base condenses readily with benzyl, forming a coloured azonium compound; and it yields colourless, non-oxidisable anhydro compounds with formic and acetic acids, thus showing all the characteristics of a mono-substituted orthodiamine. This result, taken in conjunction with the presence of two paratolylimido groups in the original substance, as shown by its decomposition by acids, proves that the leuco base is a diparatolyltriimidotoluene. This formula would represent the leuco base as an amido derivative of diparatolylparatolylenediamine. The diparatolylparatolylenediamine was accordingly prepared by heating hydrotolquinone with paratoluidine and zinc chloride and submitted to comparison with the leuco base. A marked similarity in appearance and properties was observable, entirely in accordance with the view that the latter is the amido derivative of the former. Moreover, the diparatolylparatolylenediamine was converted by oxidation into toluquinonediparatolylidiamine, and this substance showed a striking similarity in its appearance and in all its properties to Barsilowsky's base. There could, therefore,

be little doubt that the tolylamido groups in the leuco base and the tolylimido groups in the original compound occupy the para position to each other, and that consequently the constitution of the Barsilowsky base is that given above, whilst its leuco compound must be represented by the formula  $C_6H_2(CH_2)(NH_2)(NHC_6H_4)_2$  [1 : 4 : 3 : 6]. In agreement with this conclusion, the synthesis of Barsilowsky's base was effected by oxidation of a mixture of orthamidometaparatolylamine and paratoluidine in acetic acid solution, whilst its lower homologue was prepared in a similar manner from orthamidometaparatolylamine and aniline.

*The Colouring Matter of the Indian Dyestuff "Tesu."*  
J. J. Hummel and W. Cavallo. Proc. Chem. Soc. 1894 [132], 11.

THIS yellow dyestuff consists of the dried flowers of *Butea frondosa*. The dyeing power of the flowers as sold is comparatively slight, but is increased by boiling with diluted acid, the glucoside of the dyestuff becoming hydrolysed.

### PATENTS.

*The Manufacture and Production of New Sulpho-Acids of certain Naphthalene Derivatives and of New Colouring Matters obtainable therefrom.* J. Y. Johnson, London. From "The Badische Aniline and Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 2370, February 2, 1893.

THE substances referred to in this specification are derivatives of 1'4'-naphthylamine sulphonic acid. This yields a new  $\alpha$ -naphthylamine disulphonic acid and a new amido-naphthol sulphonic acid. The colouring matters obtained from these new substances are also described. Hitherto it has not been possible to sulphonate 1'4'-naphthylamine sulphonic acid, but by converting it first into the acetyl derivative the sulphonation proceeds easily, and the acetyl group can be readily split off subsequently. By fusing the  $\alpha$ -naphthylamine disulphonic acid with alkalis one of the sulphonic acid groups is replaced by hydroxyl, forming a new amido-naphthol sulphonic acid having the following constitution:—

This acid is especially valuable, as it combines with diazo and tetrazo compounds to form colouring matters and can itself be diazotised, and, moreover, certain of the azo-dyes derived from it can be diazotised and combined on the fibre giving brownish-black, violet, and black shades. For preparing the acetyl derivative of 1'4'-naphthylamine sulphonic acid, about 5 kilos. of the acid are mixed with 30 kilos. of glacial acetic acid, 3 kilos. of fused sodium acetate, and 5 kilos. of acetic anhydride, and boiled under an inverted condenser for about eight hours until a test no longer yields a diazo compound with nitrous acid. The excess of acetic acid and acetic anhydride is then distilled off and the residue is sufficiently pure for further use. In order to purify it, it is dissolved in just sufficient water and precipitated with sodium sulphate, when it forms a white crystalline powder. The same compound can also be produced by sulphonating  $\alpha$ -acetonaphthalide, but the product then contains certain isomeric acids. In order to obtain the disulphonic acid the acetyl compound produced as above is mixed with 40 kilos. of fuming sulphuric acid containing about 30 per cent. of  $SO_3$ . During mixing, the temperature is kept between  $0^\circ$  and  $5^\circ$  C., and the melt is afterwards kept at about  $20^\circ$  to  $30^\circ$  C. for 12 to 15 hours, until a sample is completely soluble in cold water. The mixture is then poured on to 50 kilos. of ice and the whole boiled in order to split off the acetyl group. On cooling, a crystalline precipitate separates out, which may be purified by recrystallisation from brine. The same acid may be obtained, but

mixed with other isomers, by sulphonating  $\alpha$ -acetonaphthalide with five times its weight of the fuming sulphuric acid employed above. The compound is obtained as the acid sodium salt, and is converted into the amido-naphthol sulphonic acid as follows:—About 150 kilos. of caustic soda and 50 litres of water are heated to  $170^\circ$  C., and 50 kilos. of the acid sodium salt are added. The temperature is kept between  $160^\circ$  and  $220^\circ$  C. for about an hour, until successive tests dissolved in water and acidified with hydrochloric acid show no increase in the amount of precipitate. The melt is then allowed to cool, broken up, and added to a mixture of 450 kilos. of ice and 600 kilos. of 30 per cent. hydrochloric acid. The amido-naphthol sulphonic acid separates out as a greyish-white crystalline precipitate, which can be purified by recrystallisation as sodium salt or by dissolving it in soda and precipitating with acetic acid. It dissolves with difficulty in cold water, and on treatment with nitrous acid yields a diazo compound in orange-yellow needles. A violet-blue for un mordanted cotton is produced by preparing the tetrazo compound from 18.5 kilos. of benzidine, pouring this into an ice-cold dilute soda solution, and immediately adding a solution of 48 kilos. of the new amido-naphthol sulphonic acid. After stirring about four hours, filter-press and dry. The colouring matter thus obtained gives shades fast to washing and light and tolerably stable to acids. It can be diazotised on the fibre and combined with amines and phenols and their derivatives, giving brownish-black, violet, and black shades, some of which are very fast to washing, light, and acids. The combinations can, of course, be varied in a similar manner to the methods usually employed for the preparation of disazo dyestuffs.—T. A. L.

*The Manufacture and Production of New Azo-Dyes, and of a Component for Use in their Manufacture.* J. Y. Johnson, London. From "The Badische Aniline and Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 2614, February 6, 1893.

ARMSTRONG and WYNNE (this Journal, 1890, 800—801, and Proc. Chem. Soc. 1890, 128) describe the preparation of a  $\beta$ -naphthylamine disulphonic acid by sulphonating 2'4'-naphthylamine sulphonic acid. By fusing this disulphonic acid with caustic alkalis a new amido-naphthol mono-sulphonic acid is obtained having the formula—

About 50 kilos. of the sodium salt of the  $\beta$ -naphthylamine disulphonic acid are fused with 150 kilos. of caustic soda and 30 litres of water at about  $180^\circ$  C. for an hour, or until successive tests show no increase in the amount of precipitate when samples are dissolved in water and treated with hydrochloric acid. The melt is then worked up as in the preceding patent. The new amido-naphthol sulphonic acid forms a greyish or white crystalline powder, soluble in hot, sparingly soluble in cold water, almost insoluble in alcohol. It combines readily with diazo and tetrazo compounds to form azo dyestuffs, and certain of these can be diazotised on the fibre and combined with amines and phenols and their derivatives. The combinations of the amido-naphthol sulphonic acid with diazo and tetrazo compounds can take place in either acid or alkaline solutions, in the former case giving redder or yellower, and in the latter blue or more violet shades.—T. A. L.

*The Manufacture or Production of Derivatives of Hydroxyanthraquinones.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 2695, February 7, 1893.

THE specification describes the preparation of the  $\alpha$ - and  $\beta$ -nitro-alizarins and of their isomers and derivatives. The direct nitration of alizarin in sulphuric acid does not give a good yield of  $\beta$ -nitro-alizarin. This substance is, however,

readily formed by nitrating the boric ether of alizarin and subsequently hydrolysing the product. About 10 kilos. of crystallised boric acid are stirred into a solution of 10 kilos. of alizarin in 200 kilos. of sulphuric acid of 66° B. After cooling, 3 litres of nitric acid of 42° B. are added at about 0° C. The melt is allowed to stand several hours, and is then poured into cold water, the precipitate filtered off and dissolved in soda-lye. The alkaline solution, after having been heated to boiling, is decomposed with hydrochloric or sulphuric acid, when the  $\beta$ -nitro-alizarin separates in a pure state. In a similar manner the  $\beta$ -nitro derivatives of flavopurpurin, anthrapurpurin, and alizarin bordeaux may also be obtained. By employing the arsenic acid ethers, however (Eng. Pat. 12,580 of 1892; this Journal, 1893, 596), the nitration proceeds differently, resulting in the formation of the  $\alpha$ -nitro derivatives. About 10 kilos. of alizarin are dissolved in 200 kilos. of sulphuric acid and 10 kilos. of solid arsenic acid are stirred into the solution. After cooling, 3 litres of nitric acid are slowly added at about 0° C., allowed to stand for several hours, and then poured into cold water. The precipitate is filtered off, dissolved in soda lye, boiled, and decomposed with an excess of sulphuric acid, and the boiling is continued until the whole of the arsenic ether of the  $\alpha$ -nitro-alizarin is decomposed, which is the case when a sample dissolves in soda-lye with the characteristic violet colour of  $\alpha$ -nitro-alizarin. The precipitated dyestuff is then filtered off and washed. By applying the same method to flavopurpurin, anthrapurpurin, or to alizarin bordeaux, the corresponding  $\alpha$ -nitro derivatives of these compounds may be obtained.

—T. A. L.

*The Manufacture and Production of New Acid Colouring Matters.* J. Y. Johnsen, London. From "The Badische Anilin and Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 3487, February 16, 1893.

THIS is an extension of Eng. Pat. 4476 of 1888 (this Journal, 1889, 280) and of Eng. Pat. 10,619 of 1891 (this Journal, 1892, 514), both of which refer to colouring matters of the "Nile blue" series. The present specification describes the preparation of acid dyestuffs of the same series by condensing the nitroso derivatives of dimethyl- and diethyl-*m*-amidophenol or cresol with  $\alpha$ -naphthylamine monosulphonic acids and with certain  $\alpha$ -naphthylamine disulphonic acids. Of the latter, the 1:4:2', the 1:4:3', and the 1:2':4' appear to have been used. The dyestuffs obtained from the monosulphonic acids vary according to the conditions under which the condensation is performed. These differences are best illustrated by an example. About 70 kilos. of nitroso-diethyl-*m*-amidophenol hydrochloride, 50 kilos. of 1:3'-naphthylamine sulphonic acid, and 32 kilos. of crystallised sodium acetate are thoroughly mixed together, and 150 kilos. of 60 per cent. acetic acid are then added, and the mixture is heated on the water-bath for 12 hours or until no further formation of colouring matter takes place. The melt is then diluted with 3,000 litres of water, and sufficient soda is added to dissolve the colouring matter, filtered, salted out, and collected. The colouring matter so obtained is easily soluble in water to a blue solution and dyes wool a blue colour fast to light and alkalis. A different product is obtained by decreasing or omitting the sodium acetate and using glacial acetic acid in the above melt. These dyestuffs are referred to as type A, and differ from the previous ones, which are known as type B by their instability to alkalis. Dyes of the type A are readily soluble in the form of alkaline salts, but the solutions are precipitated by acetic acid. They dye wool greenish-blue shades, which, however, are changed to reddish-violet or red by the action of alkalis. Dyes of the type B are readily soluble in water in the form of their alkaline salts, and these solutions are not or only partially precipitated by acetic acid. As already mentioned, these dyestuffs are fast to alkalis. Certain of the  $\alpha$ -naphthylamine sulphonic acids yield both types of dyes, as for instance the 1:3' and the 1:2' acids. On the other hand, the 1:3, 1:4, and 1:4' always yield colouring matters of the type B, whilst the 1:2 and 1:1' acids give dyes of the type A only.—T. A. L.

*The Manufacture or Production of Alkylated Hydroxy-naphthalene Sulphonic Acids and Colouring Matters therefrom.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 3495, February 16, 1893.

THE 1:1'-dihydroxy-naphthalene mono- or di-sulphonic acids in the form of their basic salts can be alkylated in one hydroxyl group with the usual alkylating agents by simply heating at about 105° C. If the acid salts be employed they can be alkylated in a similar manner by adding sufficient alkali to convert them into the basic salts. One molecular proportion of the acid sodium salt of 1:1'-dihydroxy-naphthalene 3:3'-disulphonic acid (so-called chromotrope acid) is heated with lime in order to convert it into the basic salt. The solution obtained is heated with one molecular proportion of ethyl bromide for eight hours to 105° C. The resulting sodium calcium salt of the 1-ethoxy-1'-naphthol 3:3'-disulphonic acid separates out, leaving any unaltered chromotrope acid in the solution. All these alkyl derivatives are to be employed in the manufacture of azo-colouring matters, and the combinations are performed in the well-known manner.—T. A. L.

*Improvements in the Manufacture of Indigo.* H. H. Lake, London. From Kalle and Co., Biebrich-on-the-Rhine, Germany. Eng. Pat. 4257, February 27, 1893.

By heating *o*-nitro-phenyl-lactoketone with a solution of sodium bisulphite to about 50° C., it is readily dissolved and converted into a soluble product. When this compound is printed on cloth, indigo is developed on the fibre by passing it through a caustic alkali bath. About 10 kilos. of *o*-nitro-phenyl-lactoketone and 15 kilos. of a solution of sodium bisulphite containing 35 per cent. of NaHSO<sub>3</sub> are heated at 50—55° C. The ketone dissolves readily at this temperature, and on cooling the new compound separates out in needles or plates. In order to produce indigo, the cloth is printed with the compound and passed through a caustic soda-lye of 18°—25° B. The results obtained are superior to those hitherto produced with artificial indigo. The goods are evenly dyed and do not rub. (This Journal, 1893, 908 and 988—989.)—T. A. L.

*Manufacture of New Colouring Matters Derived from Dioryldiphenylmethane.* J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran, St. Fons, Rhone, France. Eng. Pat. 20,979, November 4, 1893. Date under International Convention, April 13, 1893.

AN extension of Eng. Pat. 9182 of 1893 (this Journal, 1893, 756). The preparation of the following colouring matters is now claimed:—1. That from 1 molecule of dihydroxydiphenylmethane on 2 molecules of diazo combinations, of which one at least is the intermediate product from 1 molecule of tetrazo-diphenyl or tetrazo-ditolyl, and 1 molecule of salicylic acid. 2. The yellow colouring matters from 1 molecule of dihydroxydiphenylmethane and 2 molecules of the intermediate compound from 1 molecule of tetrazodiphenyl or ditolyl and 1 molecule of salicylic acid. 3. The colouring matter from 1 molecule of dihydroxydiphenylmethane, combined with 1 molecule of the intermediate compound from equimolecular proportions of tetrazodiphenyl and salicylic acid, and 1 molecule of the intermediate compound from equimolecular proportions of tetrazodiphenyl and sulphanic acid. 4. The colouring matter by combining dihydroxydiphenylmethane first with 1 molecule of the intermediate compound from equimolecular proportions of tetrazodiphenyl and salicylic acid, and then with 1 molecule of a salt of diazobenzene. All these colouring matters dye unmordanted cotton yellow.—T. A. L.

*An Improvement in the Manufacture of Printing Ink.* J. and J. Bibby, Liverpool. Eng. Pat. 12,563, June 30, 1893.

FOR the preparation of black, blue, and "analogously coloured" printing inks, the inventors claim the use of

cotton-seed oil foots as a substitute for the linseed oil and the soap ordinarily employed. In this way they considerably cheapen the varnish, and for many purposes, owing to the bluish-black colour of the foots, they state that any addition of pigments becomes unnecessary. The foots are boiled with open steam, and sulphuric acid added until the whole is neutral to litmus; the fatty acids are then skimmed off and freed from water. For a common ink, 75 lb. of the foots so prepared are heated with about 38 lb. of dark rosin and 20 lb. of lamp black ground in, in the usual manner. For better-class work, 75 lb. of the foots are mixed with about 48 lb. of dark rosin and 15 lb. of cotton pitch, and a mixture of about 10 lb. of carbon black, 18 lb. of vegetable black, 10 oz. of Prussian blue,  $2\frac{1}{2}$  lb. of "imitation" Prussian blue, and 4 oz. of Indian red, ground in as before.

The inventors also claim the *partial* substitution of the usual amount of linseed varnish by the cotton-seed foots, as described.—F. H. L.

*Manufacture of New Unsymmetric Diamido Bases and of Tetrazo Colouring Matters Derived therefrom.*  
J. C. L. Durand, E. Huguenin, and A. J. J. d'Andiran,  
Bâle, Switzerland. Eng. Pat. 20,790, November 2, 1893.

This is a further extension of Eng. Pat. 12,701 of 1893 (this Journal, 1893, 824; see also Eng. Pat. 20,301 of 1893, this Journal, 1894, 32). The new base referred to is produced by heating together equimolecular proportions of formaldehyde, tolidine, and *o*-amido-phenol hydrochloride. The resulting compound is said to have the constitution—

The new base is only slightly soluble in alcohol and is insoluble in ether and benzene. The aqueous acid solutions of its salts show a green fluorescence. It begins to melt at 75° C., and decomposes about 100° C. The tetrazo compound forms brownish-yellow flakes, and the nitrite required to produce it nearly corresponds to two amido groups. If combined with naphthionic acid it produces a red colouring matter, which dyes un mordanted cotton. By substituting dianisidine for the tolidine in the above condensation a base having similar properties is produced, of which the formula is the same as above if the two  $\text{CH}_3$  groups be replaced by  $\text{OCH}_3$  groups.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Research on the Hygroscopic Properties of Various Textile Materials.* M. T. Schloesing, jun. Bull. Soc. d'Encouragement, 1893, 718—733.

THE water retained by a hygroscopic substance, in equilibrium with the moisture of the surrounding air, depends upon the degree of saturation of the air, and the temperature, and experiments conducted without reference to these variables cannot yield precise results. In the experiments described, two methods have been employed. The first of these methods is similar to that employed by the author in a prior research upon tobacco (Comptes rend. 102). The sample of wool or silk, for instance, containing a previously ascertained proportion of moisture, which may be adjusted to the requirements of the experiment, is placed in a metal cylinder, 1.25 metres in length and 50 to 60 mm. in diameter, immersed in a water-bath, of which the temperature is kept constant to within two or three hundredths of a degree, while a slow current of air

is passed through the cylinder. An equilibrium of moisture is thus established between the air and the material at an exactly known temperature. The air thus passed through the material is received in an absorber containing concentrated sulphuric acid, and is thence aspirated to a gasometer for exact measurement. The moisture in the material is then ascertained. The bath employed accommodates four tubes, each connected with an absorber and a gasometer.

An example is given in which three samples of Indian cotton, having an average percentage of moisture of 5.75, were found to be in equilibrium of moisture with air at 31° 88', having a fraction of saturation of 0.447. In the formulae given  $f_\theta$  expresses the fraction of saturation, and—

$$f = \frac{11m}{1 + V \frac{11 - h - Ft}{p(1 + \alpha t)} 0.8047 760}$$

in which  $f$  is the tension of the vapour in the air that has passed through the material;  $f_\theta$ , the maximum tension of water vapour at  $\theta^\circ$ ;  $11m$ , the mean barometric pressure reduced to zero;  $11$ , the same at the end of the experiment;  $\theta$ , the mean temperature of the bath during the experiment;  $V$ , the volume of air aspirated into the gasometer;  $h$ , the excess of external pressure over that in the gasometer at the same moment;  $Ft$ , the maximum tension of aqueous vapour at temperature  $t$ ;  $p$ , the weight of water absorbed by the sulphuric acid;  $\alpha$ , the coefficient of dilatation of the gas. 0.8047 represents the weight of a litre of vapour at  $0^\circ$  and 760 mm. pressure. The special values for these experiments, leading to the result stated, are given.

The second method of experimenting consists in placing the material in contact with air of known content of aqueous vapour for a considerable time. This may be done in various ways, but that preferred is similar to the method employed by Regnault in verifying the hygrometric properties of air. It is based on the property of sulphuric acid, of certain dilutions, to absorb or give off moisture in proportions determinable by independent trials at given temperatures. In the instance given, a few cubic centimetres of sulphuric acid of the composition  $\text{SO}_3 + 18\text{H}_2\text{O}$  are placed in a litre flask, and over the acid are suspended the samples of material under trial, the flask being closed with a rubber stopper, and immersed in a bath kept rigorously at a constant temperature of 24° C. for five days. This method was used as a control upon the first, and the results obtained were pretty closely accordant. Three samples were tried, of American, Egyptian, and Indian cotton respectively, and yielded 10.97, 11.28, and 11.85 per cent. of moisture, the "fraction of saturation" of the air being 0.83 under the conditions stated. Series of experiments were made, of which the results are given in five pages of tables, for temperatures varying between 12° and 35°, and for different degrees of saturation of the air, on samples of the three kinds of cotton named; on double-milled wool (croisées) of Buenos Ayres; on merino wool of Port Phillip; on raw ungnunged silk, and other samples washed, of the Cévennes, and of China. The results obtained, reduced to the three temperatures of 12°, 24°, and 35°, are also shown by curves, in which the abscissæ are taken for the percentage of moisture in the material, and the ordinates for the fractions of saturation of the air in which the experiments were made. (See Figs. 1 and 2.)

It will be observed that all the curves have the same general trend. Also that the three kinds of cotton tested show marked differences. The ungnunged raw silk, owing to removal of gummy matters, comes out as less hygroscopic than the raw *fera* silk (i.e., raw silk which at most has been submitted to washing with or without soap, and to bleaching). The two specimens of wool give sensibly equal results.

The influence of temperature upon the moisture absorbed for the same fraction of saturation of the air, is but slight. This has been found to be true for other hygroscopic substances, such as tobacco, and also, according to Regnault and Sorel, solutions of sulphuric acid. It is pointed out, as

Fig. 1.

Fig. 2.

a result of these researches, that the degree of humidity of the air in which such operations as spinning and weaving are conducted, is of importance in relation to the condition of the textiles treated.—E. S.

Vegetable Silks, and particularly the Kapok of India (*Bombax pentandrum* and *Eriodendron anfractuosum*). J. J. Arnaudon. Monit. Scient. 7, 1893, 695—697.

UNDER the names vegetable silk, silk grass, silk cotton, &c. are grouped in commerce several products consisting of the bristly hairs or down surrounding the seeds of various plants. The author enumerates these plants, and states

that somewhat similar products may be obtained from poplars, willows, and certain species of acacia. Kapok is the name given to the bristly fibre which surrounds the seeds of the plants mentioned in the title. The properties of this fibre have been known since the year 1600. The trees commence to bear fruit and to produce the fibre when three years old, and they grow best at an altitude of 6,000 feet. They attain to the height of 100 feet; the first leaves are oval, and are succeeded by compound leaves of three to nine leaflets; the capsular fruit is as large as a small pear, and contains seeds the size of a small pea, and of a brown colour, surrounded by the fibrous envelope. The plant cannot thrive in a cold climate.

The best kapok is grown in Java; other qualities come from Sumatra, India, and Ceylon. It is only utilised to any extent in Australia, where 8,600 bales were imported in 1886, of which 7,991 came from Java. It is used for making wadding and hats, also for stuffs to imitate beaver, and mixed with rabbits' fur for costly fabrics, such as are made into turbans, mantles, &c. It has been tried also for dressing wounds.

This fibre may replace cotton in the manufacture of a fulminating powder, prepared by the action of nitric acid upon it. The nitrated kapok can be so treated as to yield a "vegetable silk" perhaps capable of being spun and mixed with animal silk.

The kapok thread measures 135–150 millimetres in length. Treated with alcohol and dried at 100° C, it loses 12 per cent. of its weight; of this 7 per cent. consist of substances soluble in alcohol. If the alcoholic extract be evaporated and the residue again treated with alcohol, a viscous mass is obtained consisting of oily globules mixed with a substance which yields volatile acicular crystals.

If the kapok fibre is treated with hot water it acquires an increased affinity for colouring matters. Indigo extract, azo scarlets, and bordeaux only yield very fugitive colours. Magenta dyes it better, and Bleu de Lyon, Malachite green, Metanil yellow, Phosphine, &c., give fairly fast shades.

#### *The Tendering of Cotton Fibre by Tartaric Acid.*

A. Scheurer. Bull. Soc. Ind. Mulhouse, 1893, 248.

See under VI., page 148.

### PATENTS.

*Improved Manufacture of Sheet Material, specially suitable for use as Label Cloth and Bookbinders' Cloth.* E. J. Goodwin, Manchester. Eng. Pat. 22,566, December 8, 1892.

A TEXTILE fabric or cloth, of close texture, is subjected to the action of sulphuric acid of about 115° T., so as partly to parchmetise the fibres and more or less completely close the interstices without destroying the texture of the cloth. The excess of acid is removed by washing, with or without previous treatment with alkali, and the washed material is subjected to pressure between calendering rolls, whereby a finished appearance is imparted, and the closing of the interstices completed. The material may be suitably dyed if necessary.—E. G. P. T.

*A New or Improved Method of Treating Canvas, Shirting, Silks, Paper, and like Substances for the Purpose of Rendering the same Sensitive to Light.* G. J. Junk, Berlin. Eng. Pat. 21,249, November 8, 1893.

See under XXI., page 173.

## VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

*A New Direct Grey.* Report by T. Baumann on a Paper by M. Petzold. Bull. Soc. Ind. Mulhouse, 1893, 221.

See under IV., page 143.

*The Quinone-oximes in Steam Colours.* M. Prud'homme. Bull. Soc. Ind. Mulhouse, 1893, 230–231.

DINITROSORESOREINOL, and the quinone-oximes generally, can be dyed by means of iron, copper, nickel, or cobalt mordants, i.e., by salts of metals which form more than one oxide; whereas they do not form insoluble alumina lakes. Hitherto these compounds have found no use in steam colours, the lakes with the above-mentioned salts being too quickly produced.

Solutions of potassium ferro- and ferricyanide heated to boiling with dinitrosoresoreinol, liberate hydrocyanic acid and deposit a green precipitate containing iron, but in which the ordinary tests for iron do not serve for the detection of that metal.

At the author's request, A. Scheurer has made certain experiments with steam colours. The colour consisted of fixed quantities of dinitrosoresoreinol and gum tragacanth, with varying amounts of ferro- or ferricyanide. The ferricyanide gives dark green shades, and this salt is to be preferred in practice. The ferrocyanide yields browner shades. One hour is the best time for steaming. The colour is fast to soap; the addition of calcium acetate, acetic acid, or sodium bicarbonate to the printing colour gives dull reddish shades not fast to soap.

Owing to the fact that dinitrosoresoreinol is somewhat insoluble, the colours have rather a dull and streaky appearance. Possibly this defect might be obviated by first heating together the gum and dinitrosoresoreinol, allowing to cool, and then adding the ferricyanide.—R. B. B.

#### *The Tendering of Cotton Fibre by Tartaric Acid.*

A. Scheurer. Bull. Soc. Ind. Mulhouse, 1893, 248–250.

In 1858, Grace Calvert noticed that the destructive action of organic acids on cotton is greater when dry heat is subsequently applied than when the material is steamed. (Bull. Soc. Ind. Mulhouse, 29, 208).

The author's experiments confirm this view, in so far as they show the energetic action of dry heat. A first series of experiments in which the printing colour contained—

	Grms.
Tartaric acid .....	75
Gum solution .....	925

gave no very definite results, merely a general indication that the tendering effect varies with the humidity of the air in the drying chamber. The tendering was in no case as great as was expected from previous results.

In a second series of trials the cotton, before drying or steaming, was immersed for half an hour in a boiling solution of sodium carbonate (10 grms. per litre). The tendering effect was thus greatly increased. The results of dynamometric tests are set forth in the form of a table, and the principal conclusions to be drawn are: (1) drying for quarter of an hour on a roller at a temperature of 110° weakens the fibre very little less than steaming for 1½ hours at 98°–99°; (2) drying at 40°–50° does not perceptibly tender the cotton more than drying in the cold; (3) the amount of tendering after steaming is shown to be about 25 per cent.—R. B. B.

*Tendering of Cotton Goods by the Iron Mordants used in Dyeing.* A. Scheurer. Bull. Soc. Ind. Mulhouse, 1893, 245–248.

EXPERIMENTS were made with two mordants, pyrolignite of iron alone, and pyrolignite of iron together with aluminium acetate. Dynamometric trials were made of the

resistances, after suspension for 12 hours in moist heat, followed either by a simple washing with water, or by "cleansing" with solutions of phosphate or silicate of soda or with lime. A second series of samples was prepared in the same way and then steamed for one hour. The results of the trials are given in the form of a table, and certain conclusions are deduced therefrom:—(1) the tendering does not vary directly, as the concentration of the mordant; (2) the presence of aluminium acetate has little effect; (3) the tendering effect with the iron mordant employed is approximately as follows:—

	Warp.	Weft.
	Per Cent.	Per Cent.
After fixing (ageing).....	15	15
After cleansing with silicate .....	20	50
After cleansing with phosphate.....	50	25
After cleansing with lime, at 50°.....	20	30
After cleansing with lime, boiling.....	30	40

The difference between warp and weft is explained by the greater tension of the latter, whereby a resistance may be offered to the penetration of a thick colour. The phosphate result is probably due to an error.

In another series of experiments the tendering in each case is shown to be about 25 per cent. (warp) whatever the cleansing agent employed.—R. B. B.

*The Dyeing of Indigo Blue combined with other Colouring Matters.* M. Polonovsky and J. Nitzberg. *Monit. Scient.* 7, 1893, 685—689.

Owing to the brilliancy and comparative fastness of the shades produced, indigo is preferred to all other colouring matters for dyeing blue on cotton, and this, in spite of certain defects, notably its property of "rubbing," and the fact that it is not perfectly fast to soap nor to atmospheric agencies. As the cost of indigo is somewhat great, especially for deep shades, many efforts have been made to combine this colouring matter with others less expensive, and by this means to produce equally good and fast colours at a decreased cost. The authors, who have had the opportunity of studying and applying several of these combinations, give a critical *résumé* of the devices most largely employed.

Two kinds of processes may be distinguished according as the supplementary colour is applied before ("bottoming") or after ("topping") the indigo vat. Also in one case, viz., the indigo-indophenol vat, the two colouring matters are applied in one operation. In this article the various processes are briefly described, commencing with the least rational.

1. *Topping with Magenta or Methyl Violet.*—The cotton is taken from the indigo vat, brightened with sulphuric acid, dyed in a cold solution of magenta or violet, aired, wrung out, and dried. The basic colours are very fugitive, and are removed from the fibre by washing.

2. *Bottoming with Catechu.*—The cotton is worked for one hour at 90° C. in a bath containing 3 per cent. catechu, the steam turned off, and the cotton allowed to remain in the bath over night. The next day it is taken out and worked three-quarters of an hour at 70° with 1 per cent. sodium bichromate, dried, and entered into the indigo vat. The ground of catechu is fast to washing, alkalis, and acids, but does not to any extent increase the depth of shade, and its yellow tint renders the blue dull and greenish.

3. *Bottoming with Oxide of Iron.*—The cotton is worked in ferrous sulphate solution, and then in very dilute bleaching powder solution. Ferric oxide is precipitated on to the fibre; this ground is cheaper than catechu, possesses all the defects of the latter, and is much less fast to acids.

4. *Bottoming with "Half black."*—The "half aniline black," produced as described below, has a bronze tint, but is transformed by passing through an alkaline bath into a deep blue, similar to vat blue. The alkaline bath is here replaced by the passage through the alkaline indigo vat. To dye 50 kilos. cotton: to 700 litres cold water add 1.25 kilos. aniline, 5 kilos. hydrochloric acid, 2.5 kilos. sodium bichromate, and 0.75 kilo. ferrous sulphate. Work 40 minutes in this bath, wash to remove every trace of acid, steam, and top with indigo. There is a saving of cost, and the shade is equal to pure indigo. But, like aniline black generally, it "greens" on exposure to air, is not fast to acids, and has a tendency to be uneven.

5. *Topping with Indigo Substitute.*—Indigo substitute is a preparation of logwood extract oxidised by sodium bichromate. After dyeing a medium shade in the indigo vat, the cotton is treated with dilute acid to remove lime, and washed free from acid. It is then mordanted with stannous chloride and dyed in a cold bath containing 12 kilos. of colour for 700—800 kilos. water; this bath serves for a large number of dyes, being replenished with the colour after each lot. By this treatment very dark shades are obtained at a relatively small cost. But the dyeing is apt to be uneven, the colour is very sensitive to acids, and becomes duller on washing.

6. *Topping with Benzozaurin R.*—If this direct cotton colour is used the cotton is washed on coming from the vat, and dyed in a bath containing 1.2 per cent. benzozaurin R and 4 per cent. sodium carbonate, and the shade may be rendered faster by a subsequent passage through very dilute copper sulphate solution. Good dark shades cannot be obtained by this method, and there is considerable loss of indigo in the dye and copper sulphate baths.

7. *Bottoming with Paraphenylene Blue.*—To the dye-bath heated to 60—80° C. add 1.5—2.5 per cent. paraphenylene blue and 10 per cent. salt, and work the cotton one hour. The bath is not completely exhausted, and for each subsequent lot one-third of the above weight of colour and half the weight of salt are sufficient. The colour is fixed by passing through a hot solution containing 1.5—2 per cent. potassium bichromate and 4 per cent. copper sulphate, and the cotton, after washing, is entered into the indigo vat. This ground is fast to alkalis and acids, but less fast to washing than indigo, and gives dull shades.

(8.) *Indigo-Indophenol Vats.*—The fact that indophenol can be applied by the same method as indigo, together with its less cost and its fastness, has caused some dyers to replace pure indigo vats with the mixed indigo-indophenol vats. Either hydrosulphite, ferrous sulphate, or zinc powder vats may be employed. The mixed vats as used by M. A. Vuillemin at Colmar are thus prepared:—50 kilos. indigo are ground to a paste with 15—18 kilos. indophenol and 200 litres water. The paste obtained serves for the preparation of 20 vats, each containing 700 litres water. Into a vessel of 200 litres capacity is put one-twentieth part of the paste, with 12 kilos. of lime previously slaked in 50 kilos. hot water; the mixture is stirred and allowed to settle for 24 hours.

The dye-vat is then prepared as follows:—It is filled three-quarters full of water, and the contents of the last-mentioned vessel are added, the whole well stirred, and allowed to settle for 6 hours. The vat is then ready for dyeing 25 kilos. cotton yarn. After 6 hours' rest another 25 kilos. can be dyed, and so on, until the vat is exhausted. The process with zinc powder vats is very similar.

In the opinion of the authors the economic advantages of the mixed vat are not sufficiently certain to compensate for its defects, viz., the sensitiveness of the colour to acids and to chlorine. The colour is extracted by cold alcohol.

All the processes described have certain defects. The requirements for a dyestuff to replace indigo are fastness, brightness of shade, and even dyeing, and, as indigo tends to dye a greenish-blue, the necessary addition must be a red, pink, or violet.

*Red Colouring Matters.*—The direct cotton reds are not sufficiently fast. St. Denis red is not fast to light. Alizarin

red is too costly, and too much indigo is required to cover its red colour.

*Pink Colouring Matters.*—Alizarin pink has been employed. A paste is made containing alizarin, aluminium hydrate, neutralised sulphated castor oil, calcium acetate, acetic acid, and pyrolignite of iron. The cotton is worked in a bath made up with this paste, and the bath gradually heated to 90° C. A fall fast pink is obtained, but is too costly for general use as a ground for indigo.

*Violet Colouring Matters.*—*Alizarin Violet.*—This the authors declare is by far the most satisfactory addition to vat indigo, although it is as yet little known to dyers. Great care is required in conducting the operations, as regards proportion of materials, time of dyeing, &c. One method, said to produce a shade identical with a deep vat blue, is described in detail. The cotton is first worked in a bath containing 1,600 litres water at 50° C. and 6 kilos. sumac extract. For each subsequent lot 3 kilos. extract suffice. After steaming, the cotton is passed through pyrolignite of iron at 1·4 B., again steamed, and worked three-quarters of an hour in chalk water, washed thoroughly, and is then ready for dyeing. The dye-bath contains 7 per cent. "alizarin for violet." Work three-quarters cold, raise to 70–75° C. in 2 hours; the bath is then exhausted. Rinse, air, and work in indigo vat until the desired shade is obtained. The quantity of indigo required is one-third of that necessary to give the same shade alone.

If the sumac extract is replaced by sulphated castor-oil neutralised with ammonia, the shades are more brilliant, but the cost of production is greater.

The blue "bottomed" with alizarin violet possesses all the best qualities of pure indigo blue. It is almost perfectly fast to alkalis, acids, and light. The authors state also that by adopting this process a saving of 40 per cent. of the cost may be effected.—R. B. B.

#### *Improvements in Turkey-Red Dyeing.* J. Mullerus. Chem. Zeit. 1893, 316–317 and 374–375.

THE author discusses the technical value of the processes of dyeing Turkey-red by means of soluble alizarin compounds, devised respectively by Schlieper and Baum (this Journal, 1884, 61), Baldensperger (sealed note of May 1886, opened 1891, Soc. Ind. Rouen; this Journal, 1892, 237), Erban and Specht (Ger. Pat. 54,057), and Schaeffer (Eng. Pat. 20,910 of 1891; this Journal, 1892, 237).

In the first of these, which was the earliest of the kind to be published, a bath of lime-water is employed for the conveyance of the alizarin to the alumina-mordanted cotton. The author questions the efficacy of this, seeing that it is generally held that the calcium alizarate, which is thus formed, is insoluble in water. He declares that the process, so far as he can ascertain, has not been adopted by any Turkey-red dyers other than its originators, and he is of opinion that, if it, as it has been described, forms the basis of a successful method of dyeing, an important part of it has been withheld from the published account.

The process of Baldensperger, which in order of discovery comes next, and which is probably the first in which a soluble (alkali) alizarin compound has been employed, utilises ammonia to dissolve the alizarin. The lime essential for the production of the red colour-lake is, in this process, added in the form of a soluble calcium salt (calcium acetate, for example) to the dyebath in small quantity only, to avoid precipitation. The author cannot speak favourably of the results obtained by this method.

Erban and Specht employ alkalis as solvents for the alizarin, and reverse the usual order of the principal dyeing operations (namely, first mordanting and then dyeing), making the application of the dye precede that of the mordant. Their process consists in passing the cotton to be dyed through an alkaline solution of alizarin, drying, passing through a bath of a mordanting salt, again drying, and finally completing the combination of the mordant and

colouring matter upon the fibre by steaming. Thus, for example, the cotton is taken through a bath of—

500 grms. of alizarin,  
2 litres of water,  
125 cc. of ammonia solution,  
240 cc. of Turkey-red oil (75–80 per cent.), and  
8 grms. of sodium stannate,

dried in an ageing room (*i.e.*, by hot air), padded in a bath of—

3,100 cc. of water,  
550 cc. of aluminium acetate at 16° B., and  
85 cc. of calcium acetate at 21° B.,

again dried, steamed for two hours (one hour under one atmosphere's and one under 1½–2 atmospheres' pressure), and, finally, soaped and washed. Following this process the author succeeded in dyeing short fents tolerably well, but, on a larger scale, entirely failed to get a passable colour, this being browner, duller, looser, and more uneven than that obtained on the smaller scale. Using aluminium "bi-sulphite" instead of aluminium acetate in the mordanting bath a rather better colour was produced.

Excepting that the solution of the alizarin is effected with borax instead of with ammonia, the process of Schaeffer appears to be identical with that last described. A slightly richer and brighter red than is obtained by that method is, however, producible by it.

Experiments were further made with a sodium carbonate solution of alizarin, and with an ammoniacal solution of the same dye, to which sodium aluminate was added, but the results were in both cases more or less unsatisfactory.

The author concludes that it is impossible to obtain by the above processes a colour which can compete with the red which is ordinarily dyed. The processes may find advantageous employment in the dyeing of cloth which is to be subsequently printed dark colours or black. But probably the only application of any importance which can be made of them, is in the dyeing of fabrics for discharge printing, the red colour-lake in the partially-formed state in which it exists before steaming being discharged with especial ease. Borax and soda are to be preferred to ammoniacal solvents for the alizarin in the dyeing of the red for this purpose.

Incidentally it is mentioned that very bright and fast alizarin pinks and other colours may be produced by Erban and Specht's method, and that the proprietors of one of the German dye-manufacturing concerns have considered the process sufficiently valuable to acquire the patent rights of it.—E. B.

#### *Improvements in Turkey-Red Dyeing.* Erban and Specht. Chem. Zeit. 1893, 542–543.

IN reference to the preceding paper of Mullerus' (see preceding abstract), it is pointed out that the present authors have patented the employment, in their process of dyeing, of the following compounds as solvents of the alizarin:—Ammonia, ammonium carbonate, alkaline hydroxides, and carbonates; alkali salts having an alkaline reaction, such as sodium phosphate, borax, sodium silicate, sodium aluminate, soaps, Turkey-red oils, &c.; and organic bases (amines). It will thus be seen that the process of Schaeffer, to which allusion is made in the paper in question, is closely related to that of the authors.

Mullerus' assertion that he was unable with the authors' process to obtain on a larger scale results equal to those he obtained on a small scale, is severely criticised.—E. B.

#### PATENTS.

##### *Improvements in or relating to Calico Printing.* L. Lang, Manchester. Eng. Pat. 2009, January 30, 1893.

THE object of this patent is to produce coloured designs with a less number of engraved rollers than heretofore, and with a better effect. One roller carries the outline of the subject, and on this roller the shades and shadows are also produced by stippling or line engraving. The outline and the shades are thus printed at one impression, and the

various colours are afterwards applied by separate rollers, which are only engraved just sufficiently to receive the colour and impart it to the fabric.

In producing a coloured design according to this invention, it is necessary that the colour of the outline and the first colour afterwards applied should match, e.g., black outline and slate colour to follow, or brown outline and chocolate to follow.—R. B. B.

*Improvements in the Process of Dyeing.* O. P. Amend, New York, U.S.A. Eng. Pat. 18,232, September 28, 1893. (Under Internat. Convention.)

The fibre is treated with a cold solution of chromic acid together with some other acid which must be of a non-oxidising character. The product is described as an insoluble chromate of the fibre. It is further subjected to the action of a reducing agent in solution, e.g., ferrous sulphate, cuprous chloride, or a bisulphite. The prepared fibre may be finally dyed by any well-known process.

The invention is described as that of the production of "a fast mordant on fibrous substances."—R. B. B.

*Improvements in and connected with Varnishing in Colours.* J. Perl, Berlin, Germany. Eng. Pat. 21,455, November 10, 1893.

See under XIII. B., page 164.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Oxidation of Nickel Sulphide.* P. de Clermont. Comptes rend. 1893, 117, 229—231.

When recently-precipitated nickel sulphide which has been well washed with hot water is exposed in a thin layer on filter-paper to the air, it gradually loses its moisture and at the end of 24—48 hours changes colour from black to apple-green. The product is detached from the filter, extracted with boiling water until nothing more is taken up, and the insoluble residue treated with dilute hydrochloric acid, which leaves a residue of sulphur undissolved. The hydrochloric acid solution contains the basic sulphate,  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$ , the constitution of which has been determined by Fremy, and which has been described by Tapputi, Berzelius, and Habermann. The green aqueous solution contains principally the basic sulphate, together with the normal sulphate and a little free sulphur.

When nickel sulphide is covered with a layer of water the oxidation extends over several months, and more normal sulphate and less basic sulphate are produced than in the case last cited.

In conclusion, the author states that nickel sulphide cannot be completely oxidised in the air, but the residual sulphide enters into a stable combination with the normal sulphate.—A. R. L.

*Liquid Chlorine.* M. Fribourg. Bull. Soc. d'Encouragement, 1893, 706—707.

Liquid chlorine is prepared on an industrial scale at M. Pechiney's works at Salindres, where, by means of a pump, the body of which is formed as a U-tube, in cast-iron lined with lead, having sulphuric acid and petroleum respectively in its two limbs, acting as pistons, the gas is compressed into iron or steel cylinders, each weighing about 100 kilos., and capable of containing 50 kilos. of the liquid chlorine. Two bronze stopcocks are provided to each cylinder, one serving for delivery of the gas, and the other, connected to a tube reaching to the bottom of the vessel, for charging, and also for discharging if required, the liquid chlorine. It is stated that neither iron, copper, nor lead are attacked by dry chlorine, and that vessels for containing the liquid have suffered no deterioration after two years' use.

The density of liquid chlorine is about 1.33, and 50 kilos. give nearly 15,000 litres of the gas. The pressure of the liquid at 35° is 10 atmospheres, and the containing cylinders are tested up to a pressure of 100 atmospheres. The author describes a vessel for containing liquid chlorine, suited for laboratory use, consisting of a wrought iron bottle, with double stopcock, from which the gas or the liquid may be obtained at pleasure, means being provided for connecting one of the stopcocks to a tube conveying the gas. Reference is made to Faraday's original experiment in liquefying chlorine; and the advantages of liquid chlorine over bleaching powders and liquids, as to convenience in application and facility in transport, are stated.—E. S.

*The Separation of Volatile Fatty Acids.* M. Wechsler, Monath. f. Chem. 14, 162.

See under XXIII., page 178.

## PATENTS.

*Improvements in Electrolytic Apparatus.* F. Andrioli, Brixton, Surrey. Eng. Pat. 1661, January 25, 1893.

See under XI., page 160.

*Improvements in or applicable to Brine evaporating Pans.* J. Parks, Northwich. Eng. Pat. 2400, February 3, 1893.

In this invention brine is evaporated by means of steam instead of heating the pan direct by fire, and with a view to economy of fuel a second pan is built directly over the first and heated by the steam issuing from the lower.

The accompanying illustrations show the construction of the pans in longitudinal and cross sections.

*a a* is a vessel containing water only, heated direct for the purpose of raising steam which is to boil the brine contained in the pan above. The vessel is built over a fire-grate and flues, and is provided with water pockets for increasing the heating surface. The issuing steam heats the brine pan *e e*, above which the second brine pan *f f* is situated. The two pans are separated by a diaphragm *g*.

Fig. 1.

Fig. 2.

which is deeper along the middle than on the sides, and is provided with passages or shafts,  $g^1 g^1$ , through which the steam from the lower pan ascends.

The condensed water is collected in the central channel  $g^2$ , and is used for feeding the lower evaporating vessel with pure condensed water. Through the channel  $g^2$  are also led the brine inlet pipes K, whereby the brine is heated before reaching the evaporating pans.

In order to facilitate the removal of the salt without the loss of the whole of the steam between the two brine pans, vertical partitions are introduced in the pans, which cut them up into sections, any one of which can be emptied without interfering with the others, and suitable means are provided for regulating the brine, the water, and the issuing steam.—B.

*Improvements in Apparatus used in the Concentration of Sulphuric Acid.* I. Levinstein, Manchester. Eng. Pat. 2476, February 4, 1893.

APPARATUS for the concentration of sulphuric acid, consisting of a descending series of glass vessels exposed to external heat, in which the acid is led from the spout of one vessel into the bottom of the next lower vessel through a glass tube, is described in Eng. Pat. 19,213, 1892 (this Journal, 1893, 156); but the inventor has found that these glass tubes are liable to displacement, in which case the lighter acid flows on to the surface of the acid in the next lower vessel, impairing the working of the process, besides having other inconveniences, sometimes involving the loss of the vessels. Such defects and losses are avoided by flattening the upper end of the glass tube, and so cutting away or notching one of the flattened sides that the cut-away part may fit closely against the upper vessel immediately below the spout. Or the upper end of the tube may be moulded to fit as described. A portion may be cut away sideways from the lower end of the glass tube, so that clogging may not take place.

The glass vessels are shown resting in metal basins having opposite vertical wings cast to each basin, to form shields or defences against the eddying hot gases that might otherwise come into contact with them and occasion breakage.—E. S.

*Improvements in the Method of and in Apparatus for Recovering and Concentrating Waste and Diluted Sulphuric Acid, and for Separating and Recovering other Acids in Mixture therewith.* I. Levinstein, Manchester. Eng. Pat. 2835, February 9, 1893.

THE method of concentration employed is that described in Patent No. 19,213, 1892 (this Journal, 1893, 156), according to which a series of glass vessels receives the acid to be concentrated from the "receiving tank," into which it is run from a large lead or stone tank. The glass vessels, on successively lower levels, are fed one from the other by tubes (see abstract of Patent 2476, 1893, in this Journal), and are contained within an oven, the trunk of which, according to the present invention, is formed at its end into two branches, one leading to a lead tower, and the other to an earthenware tower, both towers being filled with coke or the like, and connected to a chimney or draught-producing device. When the sulphuric acid to be concentrated contains nitrous acid, the damper in the branch leading to the earthenware tower is opened, the other branch being closed, and water is caused to trickle down the tower. The nitrous acid in the vapours is recovered as nitric acid, and may be pumped up to the top of the tower for use instead of water. When the concentration is carried out by two stages, the nitrous acid is removed and recovered as nitric acid in the first stage; but during the second concentration the vapours are led through the second branch to the lead tower. The arrangements admit of modifications according to circumstances. Thus, two concentrating ovens may be used, one connected to an earthenware tower, and the other to a lead tower. When sulphuric acid works are near, the earthenware tower may be dispensed with, the branch or trunk being put into communication with the Glover tower of such works.—E. S.

*Improvements in and relating to the Manufacture of Paints, Sulphuric and Sulphurous Acid from Protosulphate of Iron.* M. N. D'Andria, Stretford, Lancaster. Eng. Pat. 4342, February 28, 1893.

See under XIII., page 163.

*Improvements in the Method of and Apparatus for Manufacturing Cyanides, Ammonia, and Fuel Gas.* A. J. Boulton, London. From E. Cowen, New York, U.S.A. Eng. Pat. 13,069, July 4, 1893.

See under II., page 140.

*Improvements in the Manufacture of Ammonia, Sodium Hydroxide, and Chlorine, and in Apparatus therefor.* C. Kellner, Vienna. Eng. Pat. 13,722, July 14, 1893.

SODIUM chloride solution is pumped from a reservoir into a closed vessel containing a horizontally arranged series of carbon or platinum plates serving as anode to a source of electricity, while mercury at the bottom of the vessel serves as cathode. As the sodium chloride is electrolysed, an amalgam of sodium is formed, and chlorine is set free, which escapes by a tube in the cover and is conducted away for use. As the bottom of the vessel is depressed towards the centre, the amalgam flows by gravity through an aperture into a funnel tube, which conveys it on to the inclined bottom of a second vessel receiving sodium nitrate solution from an elevated reservoir. The inclined bottom is lined with corrugated iron, above which is arranged a wire grating, gilt, silvered, or platinum-coated, serving as one electrode, the amalgam being the other electrode; the electric energy developed by the pair is conducted away, preferably for relieving the electric generator connected to the first vessel. The sodium amalgam decomposes the sodium nitrate solution with formation of ammonia (which is conducted away and collected) and of sodium hydroxide. The mercury, now freed from sodium, issues from the lower end of the bottom to be passed through a cooling coil, and to be returned by a force pump to the electrolytical decomposing vessel, which it enters near the periphery of the depressed part, and follows a spiral path by a channel formed for the purpose so as to attain a whirling motion, under which conditions it becomes recharged with sodium, and the process goes on continuously until the sodium nitrate is decomposed. Provision is made for returning the sodium chloride solution for enrichment to its reservoir. It is an important condition in the apparatus that the carbon anode should present a much larger area than the mercury to which it is opposed.—E. S.

*Apparatus for the Electrolytic Production of Bleaching Liquid.* C. Kellner, Vienna, Austria. Eng. Pat. 13,723, July 14, 1893.

See under XI., page 161.

*A Method of and Apparatus for Effecting the Absorption of Carbonic Acid.* A. Müller, Nieder-Schönweide, near Berlin. Eng. Pat. 13,928, July 18, 1893.

THE gases containing carbonic acid, such as arise from the combustion of fuel or from roasting, are led to a vacant space at the bottom of an air-tight sheet-iron casing, within which a number of equidistant vertical nettings, preferably of iron wire, are placed. The netting is woven so close that it may contain, for instance, 49 small square holes per square inch. The sheets of netting are separated by a series of slats, beside which the upward current of gases has to pass, so as to bring them into strong frictional contact with the surfaces of the nettings. The alkaline liquid acting as an absorber is forced by a pump into a tube having branches communicating through small perforated pipes with spaces between clamps securing the upper part of the nettings, whereby it becomes distributed over the whole length of all the nettings in such manner that every little square is occupied by a film of the liquid. Thus the passage of the alkaline liquid is opposite in

direction to the flow of the gases. There is a pipe in the bottom of the casing to conduct away the liquid as it drips from the nettings. The spent gases, practically freed from carbonic acid, are led off from the top of the casing by connection to a chimney or other draught producer. It is stated that in this apparatus the liquid is discharged after it has been in contact with the gases for four minutes. Details of the devices used in securing the nettings and of other arrangements are given.—E. S.

*A New Cleansing Composition or Powder.* S. E. Mott, G. W. Wort, S. Wort, and E. W. Wort, London. Eng. Pat. 18,169, September 27, 1893.

The cleansing powder is composed of soda-ash and finely-ground soda crystals in various proportions.—K. E. M.

*Improvements in Apparatus for the Electrolytical Decomposition of Salt Solutions.* C. Kellner, Vienna, Austria. Eng. Pat. 19,542, October 17, 1893.

See under XI., page 162.

*A New Process for Reducing Sulphuretted Ore into Oxides and Sulphur.* L. Bemelmans, Brussels. Eng. Pat. 19,606, October 18, 1893.

The finely-crushed ores are treated in a modified Hasenclever furnace, which is divided into sections by vertical partition walls. They are at first exposed to the action of sulphurous vapours produced at the earlier stages of the process, by which means arsenic, antimony, and phosphorus are eliminated if present, and some sulphur is given off. They then pass on to the roasting zone proper, where they meet with highly-heated air, free from oxygen, and finally they descend to the hottest oxidating zone, from whence they are discharged in a completely oxidised state. A certain proportion of non-sulphuretted ore may be used if coal is added in certain proportions. The heated air necessary for the process is supplied alternately from the two chambers of a recuperator, the free chamber of which is re-heated by the combustion of some gaseous fuel, so that neither the oven nor the ore require any other heating.

The gases from the upper or disillating zone consist of nitrogen, sulphurous acid, and vapour of sulphur, together with carbonic acid and the sulphurets of arsenic and antimony in some instances. They are injected, together with hot producer gas and steam, into a reducing apparatus or recuperator, by which the sulphurous acid and free sulphur are converted into sulphuretted hydrogen. This is then cooled down, dried, and mixed with something less than half its volume of sulphurous acid, which also has been dried when necessary, but is preferably taken from the ore-roaster at a lower level. The mixture is led through heated flues, and finally injected into a condenser by means of steam jets, where sulphur separates in a solid or liquid form and water-vapour passes off.—J. H. C.

## VIII.—GLASS, POTTERY, AND ENAMELS.

*Chemical Considerations on the Pottery Industries of the United States.* K. Laogenbeck, Amer. Chem. Soc. 15, 651—655 and 695—703.

THE pottery industries of the United States are conducted on an empirical basis; the potters, on the one hand, are generally ignorant of chemistry, and the chemists, on the other, seldom have opportunities of working in or having access to the manufactories. Thus the chemists, as a rule,

have no knowledge of the potters' needs, and the collecting and analysing of thousands of new varieties of clay, which is done every year under the United States Geological Survey department, bears no industrial fruit as far as the potters' industry is concerned. The present papers were written with a view to give such a description of the chief branches of the American pottery industry as would show the chemists how to make the work of the Geological Survey available for this industry.

The most important products of the pottery industry in America are fire-clay goods, terra cotta, red ware, yellow ware, stone ware, cream-coloured ware, and white granite ware. The first two being unglazed wares, the manufacturer is less dependent upon the aid of chemistry, and they are not dealt with by the author.

*Red ware* is ordinarily formed from the same materials as are used for making bricks, and is used for door knobs, milk crocks, cooking vessels, &c. There is a practice, much to be reprehended, of using litharge or galena alone for producing the glaze, which takes up alumina and silica from the ware. The glaze thus formed is basic on the surface and hence is liable to be attacked by the acids present in cooking operations. A usual glaze is one having the following composition: 1.0 PbO, 0.09 Al<sub>2</sub>O<sub>3</sub>, 0.03 Fe<sub>2</sub>O<sub>3</sub>, 1.4 SiO<sub>2</sub>. In order to be safe against chemical action when the vessels are used for cooking, it would be better to use a glaze containing a higher proportion of acid. In burning this ware an oxidising fire must be maintained throughout to ensure a bright red colour and prevent reduction of the lead in the glaze.

*Yellow ware* is a higher class ware, and requires a higher temperature for burning. Accordingly the glaze is applied to once baked (or biscuit) pieces, and is then finished in a second fire less hot than the first. The material used belongs to the class known commercially as second-class fire clays, such as the "buff" or "blue" clays of the coal measures. The following is the composition of a typical clay of this kind, as expressed in a "rational analysis":—Clay substance, 76.05 per cent.; quartz, 19.54 per cent.; feldspathic detritus, 4.28 per cent. The material is prepared more carefully than that of the "red ware" potter, being "slipped" in a vat with mechanical plungers, then passed through a 60-mesh wire sieve or a No. 8 silk lawn, and brought to the condition of a plastic clay by evaporation or by a filter press. A class of clays known as "flint clays," which occur in rocky masses having a conchoidal fracture, are perfectly suitable in composition for making yellow ware, but are not used for the purpose owing to their intractable nature. The machinery required for wet-grinding the flint clays would not be specially expensive, but the author is of opinion that in so conservative an industry the introduction of such machinery would meet with great opposition. If a chemist wishes to introduce a new clay into the pottery industry he must be able to inform the manufacturer at what degree of heat the clay will attain "good biscuit" condition, in order that the potter may know if he can put it in the kiln along with his old ware. For the purpose of these tests a *Seger pyrometric cone* is used. These cones are made of orthoclase, marble dust, quartz, and kaolinite, and are numbered 1. to VIII. according to the proportion of the different materials employed, which determines the temperatures they will resist before "crooking over" and melting down. A common glaze for yellow ware is 1.0 PbO, 0.2 Al<sub>2</sub>O<sub>3</sub>, 2.0 SiO<sub>2</sub>. "*Rockingham ware*" differs from yellow ware only in being covered with a brown manganiferous glaze, e.g., 0.85 PbO, 0.15 MnO, 0.18 Al<sub>2</sub>O<sub>3</sub>, 1.8 SiO<sub>2</sub>. It is used for tea and coffee pots, pitchers, &c. When experimenting with clay to ascertain its uses in pottery, the chemist may make the clay into rings, which are set upright in the furnace, a little "slip" being used to make them stick. These rings can be withdrawn from time to time with an iron wire, and the action of the fire can be ascertained, at the same time that the temperature is measured by the Seger pyrometric cones. The fired pieces of clay are then removed from the muffle, covered on one side with the glaze, and baked a second time to melt the glaze, the temperature in this case being noted by the melting of a gold-silver alloy. The tint of the clay under

the glaze, and the behaviour of the glaze upon the clay, should be carefully noted and accurately described for the information of the potter.—V. C.

*Artificial Stone, Bricks, Tiles, and the like.* J. Gaskell, Rutherglen, and W. Robinson, Windle. Eng. Pat. 22,784, December 12, 1892.

See under IX., page 154.

*A Method of Lining Spigot and Socket, Flange, or Saug Pipes with Enamel, Glass, Composition, or other Material.* F. Herbert, Birtley, near Newcastle. Eng. Pat. 22,682, December 13, 1892.

The pipes, having been moulded or cast in the usual manner, are cleaned from sand, &c., the cores are removed, and the pipes are placed upon a "gantry" and caused to revolve in a furnace. A perforated tube, containing the enamel or glaze, is passed through the interior of the pipe and made to revolve, thereby distributing the enamel or glaze evenly upon the interior surface of the pipe. The heat of the furnace causes the enamel to melt and fix itself upon the surface of the pipe.—V. C.

*Improved Means for Producing Crucibles or Melting Pots.* E. J. T. Digby, Liverpool. Eng. Pat. 3661, February 18, 1893.

See under X., page 158.

*Improvements in Chamber-Kilns.* F. H. Jung, Salisbury. Eng. Pat. 18,829, October 7, 1893.

This invention has for its object the production of an intense heat with a small amount of expense and labour, the rapid drying of the bricks without discolouring them, and increasing the output of the kiln. These objects are attained by the arrangement of the heating flues and their accessories.—R. B. P.

*New or Improved Process of Etching on Glass, Porcelain, and the like.* J. Retzlaff, Steglitz, Prussia. Eng. Pat. 20,533, October 31, 1893.

In the usual method of etching upon glass surfaces, a layer of tin foil is affixed by means of paste, the pattern is then cut out in the tin foil, the exposed paste removed by means of turpentine, and the exposed surface of glass is then acted upon in the well-known manner. The process of cutting out the pattern from the tin foil is slow, requiring care and skilled workmanship. In the new process this operation of mechanically cutting out the pattern is replaced by a chemical action. Thus, in order to etch a design in relief, the method would be to transfer the design on to the tin foil in a grease pigment and then to eat away the tin foil round the greased portions by means of an acid. The tin foil in this process is attached to the glass surface by a layer of asphalt. Besides giving perfectly sharp contours to the pattern, the new process has the advantage of being specially adapted for producing large quantities.—V. C.

*Improvements in the Manufacture of Bricks, Terra Cottas, and the like.* C. Schlickeyen, Berlin. Eng. Pat. 22,280, November 21, 1893.

See under IX., page 154.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### PATENTS.

*Artificial Stone, Bricks, Tiles, and the like.* J. Gaskell, Rutherglen, and W. Robinson, Windle. Eng. Pat. 22,784, December 12, 1892.

The above are made from the waste sand, glass, and sulphate of iron produced in glass grinding and polishing, with or without the addition of a flux. If the moistened material be pressed hard, solid bricks can be produced by heating without the addition of extraneous material. On the other hand, various fluxes may be added according to the class of article required. Barytes, sulphate of lime, granite, and clay are the materials most commonly used for mixing with the waste material.—V. C.

*Improvements in the Manufacture of Bricks, Terra Cottas, and the like.* C. Schlickeyen, Berlin. Eng. Pat. 22,280, November 21, 1893.

In the manufacture of bricks, facing blocks, terra cottas, and the like, it has hitherto been almost impossible to prevent the appearance of white or yellow spots. Sometimes after burning it is found that the facing surface is so much discoloured that the block cannot be used unless it be first chemically treated, at considerable expense, or coated with colour.

The present invention prevents the formation of these spots by treatment during drying, that is to say, after the objects have been moulded and before they have been put into the kiln. On leaving the press mould the brick is cut at about  $\frac{3}{8}$  in. from the bottom, so that the slab, which has been nearly cut off adheres slightly to the brick. The brick is placed upon a drying board, which must be absolutely clean, and is preferably covered with paper free from salt or acids. The surface of the brick which is downwards is the facing surface. In the drying process the upper layers are more exposed to the action of the air, and hence the moisture, with the salts, &c., is drawn up from the lower layers. Before the article is placed in the kiln it is freed from the slightly adhering upper slab, which now contains the salts.

It is not absolutely essential to cut the brick and subsequently remove the slab as here described, as by the above process of drying, all the salts, &c. collect in the upper portion (which will be the back of the brick), leaving the facing surface free from anything which can cause a spot or stain.—V. C.

*Certain Improvements in the Preservation of Wood.* A. A. Hely, Westminster, Middlesex. Eng. Pat. 3356, December 16, 1893.

The wood is impregnated through its pores, under any well-known process, first with a strong solution of calcium bisulphite and then with a corresponding solution of caustic lime. A monosulphite is formed, which is subsequently oxidised by the action of the air to calcium sulphate, and becomes practically part of the ligneous structure.

## X.—METALLURGY.

*Researches on the Properties of Alloys.* W. C. Roberts-Austen. Second Rep. to Alloys Research Com. Inst. Mech. Eng. 1893.

The main object in view was to extend a research the author had previously made upon the application of the "periodic law" of Newlands and Mendeleeff to the mechanical properties of metals. The law, as originally expressed,

states that the properties of the elements are a periodic function of their atomic weights." It had already been shown that the effect of impurities added to gold is nearly proportional to their atomic volumes, the larger the volume of the atom the greater being its effect; and the question was, does this hold good for other metals?

It was evident that there is a direct connection between the properties of a mass and the volume of its atoms. In all probability, therefore, the introduction of free molecules of an added element must create a disturbance, the nature and magnitude of which will bear some relation to the volume of the disturbing atoms. In the present inquiry, which is conducted essentially from the engineer's point of view, great prominence is given to mechanical tests, upon the results of which the employment of materials depends. A series of experiments was made on copper, showing the influence of arsenic, antimony, and bismuth on that metal.

The passage of iron from one allotropic modification to another is accompanied not only by a change of heat capacity, but also by a change of volume. When a mass of iron cools down from a temperature of 1,000° C., or 1,800° F., it also contracts, until at the point of recalescence it suddenly expands; after which it again contracts, as it cools to atmospheric temperature. An experiment described in the previous report indicated the probability that pressure lowers the critical points of iron and steel. By compressing a piece of steel in a hydraulic press, it should be possible to obtain recalescence at a lower temperature than would be the case if the pressure were not applied. Observations were made by the eye in order to see whether such a lowering of the recalescence point could be detected in a piece of compressed steel; but it was found that lateral flow of the test piece rendered the experiment difficult, by preventing the application of a sufficient stress until after the metal had passed through its allotropic change, and had become more or less rigid. Moreover, the orifice in which the thermo-junction was placed in the specimen became obliterated by the lateral flow of the metal. One such experiment, however, showed that when the mass was heated to 1,000° C. without pressure, that recalescence occurred at 650° C., but at 620° C. with a pressure equivalent to nine tons per square inch.

Three sets of experiments in all were made, and from a study of these it was evident that the recalescence point is lowered by pressure; but it was found that this lowering is not effected unless the load is applied at a temperature well above that at which recalescence takes place.

It has long been known that when a triple alloy of bismuth, lead, and tin, which bears Newton's name, is cooled down from the molten state, there occurs, long after the metallic mass has solidified, a remarkable rise in its temperature. Experiments made show that this evolution of heat occurs generally at 46° C., or 115° F. An evolution of heat also takes place if the solid mass is cooled rapidly by quenching in water. This effect, however, disappears after the third or fourth heating, but may be restored by remelting the mass, or by raising it to a temperature just below its melting point. A suitable alloy for the experiment is the one containing 50 per cent. bismuth, 31½ per cent. lead, and 18½ per cent. tin. The appearance of the fractured surface of the mass, if broken before the evolution of heat, is plate-like, crystalline, and almost vitreous, but after the thermal change the fracture is grey, dull, and finely grained. It will be evident that the changes this alloy undergoes, present certain analogies to those which take place in steel during the hardening by rapid cooling from a high temperature, and when the metal cools slowly from bright redness.

It became interesting in the investigation to see whether the application of pressure would cause the change to take place at a lower temperature than that at which it would occur without pressure.

The result of the experiment showed that under a pressure of one ton per square inch the temperature at which the thermal change took place was lowered as much as 4° C., or 7° F., that a pressure of about four tons per square inch was sufficient to obliterate the thermal disturbance altogether. The effect of pressure in lowering the critical point in this alloy is evident, and it was interesting to ascertain whether

the compression of the mass had really prevented the alloy from undergoing the molecular change from the vitreous to the grey variety, or whether the recalescence had been so gradual that there was no sudden augmentation of temperature in the cooling mass, such as would be indicated by a marked discontinuity in the autographic curve. The die was accordingly made in halves, so that it could be rapidly opened when the pressure was released. The solid cylinder of compressed alloy was removed and fractured with as little delay as possible, but it was found that the change, though not complete, was far advanced. It is impossible to say whether the change occurs directly the pressure is removed, or during the time it has been applied.

It may be asked, what evidence has been gathered as to the mode of action of added elements? And does it appear that the atomic volume of the added element has a dominating influence on the mechanical properties of the mass in which it is hidden? The true action of an added element may readily be masked by its action as a de-oxidiser. Notwithstanding this, it is undoubtedly proved that bismuth, potassium, and tellurium—all of which have large atomic volumes—greatly lower the tenacity of copper. Arsenic, which has a larger atomic volume (13·2) than copper (7·1), confers strength on copper; but it is very certain that the limit of elasticity and the ductility of a metal are greatly influenced by the presence of such of the elements with large atomic volumes as have thus far been studied; and this fact may be of more molecular significance than the diminution of tenacity, to which, for the sake of simplicity, attention was mainly directed when the early experiments on gold were made.

The very important question now arises, may the effect of an added element mainly depend on its power of forming either a fusible or an infusible compound with the mass in which it is hidden? This is the view held by le Chatelier, who also suggests that the deleterious action of an element is due to its forming a fusible compound with the mass, whilst, on the other hand, the presence of an element which forms an infusible compound with the mass promotes the formation of a fine grain and gives strength. The whole tendency of recent work is to show that when small quantities of elements are added to a metallic mass, they behave as a gas would, and remain free. It remains to be seen at what point in the cooling of a highly heated fused mass of a metal forming a solvent an impurity would enter into combination with a portion of the mass, and what amount of impurity of a given kind has to be present in order that it may lose its individuality.

With regard to the important molecular change which may take place in a solid metal or alloy, and of which the recalescence of steel is the most striking example, it is no small gain to have ascertained that the temperatures at which such changes occur are altered by pressure; and this seems to be a conclusion which it is safe to deduce from the experiments given in the present report.

The profound change which is produced in the properties of metals by alloying them is well shown by some recent experiments by Professors Dewar and Fleming. They have examined the effect of very low temperatures on the electrical resistance of pure metals and alloys, and the results tend to prove that, if pure metals could be reduced to the absolute zero of temperature, they would offer no resistance to the passage of an electric current. This is true of soft, pliable metals like gold, and rigid ones, such as nickel. Impure metals and alloys behave very differently: the diminution of resistance by exposure to cold is very marked, but the direction of the curves representing resistance and temperature appears to indicate that the resistance at the absolute zero of temperature would still be considerable.

---

*The Chlorination of Gold Ores.* L. D. Goddall. Eng. and Mining J. 1894, 5.

THE questions to be determined in the laboratory for the treatment of an ore in the raw state are the amount of chemicals required, the time of exposure to chlorine necessary, and the fineness to which the ore must be crushed to obtain the best results.

It is very difficult to determine in the laboratory the exact amount of chemicals required in the mill; however, by making a series of comparative tests on the same sample before and after roasting, some idea may be obtained as to the relative consumption of chlorine or bromine in the raw and roasted samples.

The degree of fineness required in the crushing should be very accurately determined by making a series of experiments on 20, 40, 60, 80, and 100 mesh samples of the same ore.

*Treatment of Roasted Ore.*—The laboratory work previous to the treatment of an ore requiring roasting should be very thorough. A good plan is to make a preliminary test as follows:—A sample, carefully taken, is passed through an 80-mesh screen and assayed; 150 grms. of the ore are then roasted in the muffle in two 4-in. roasting dishes, each containing 75 grms. of ore, using the same temperature and time for each. The temperature should be the same as in ordinary oxidising roasting, starting with a dark red heat and gradually increasing to a light red at the end of the operation. From one to two hours is sufficient for most ores if properly stirred. After the roasting is completed the ore is allowed to cool, is weighed, and the loss in weight noted. The sample is now again assayed to determine the loss of gold, if any, by volatilisation. The sample is then chlorinated as usual and the tailings assayed.

This test, if properly carried out, should give a fair idea as to the applicability of chlorination to the ore when subjected to an oxidising roasting. If the extraction in the above experiment has been reasonably good, further tests should now be made with regard to the fineness of the ore required to ensure the most successful treatment. The experiment should now be repeated on 20, 40, 60, 80, and 100 mesh samples of the same ore. This is very important, as results will probably show the extraction on the different sizes to be entirely dependent on the physical characteristics of the ore. If very dense and close-grained, even if the gold is comparatively free, or if associated with pyrites, and these occur in almost microscopical crystals, then fine crushing is almost always necessary; but if the ore is naturally very porous, or capable of being made so in the roasting, then crushing to a 16-mesh to the linear inch may give as high an extraction as crushing to 80-mesh.

After determining the most suitable mesh of screen to use, the next step will be to find the most suitable temperature in roasting. Some ores containing a large percentage of sulphur, like concentrates, must be subjected to the usual slow, gradually increasing oxidising roasting. Ores containing less sulphur, or such as are partially oxidised, can be roasted in a very much shorter time, but require a higher temperature throughout.

Some ores entirely free from sulphur require a slight roasting. This is due to the fact that the gold is associated with the hydrated oxides of iron. This roasting is more properly called a calcination, as the heat used is just sufficient to expel the combined water.

The proper temperature in roasting may be determined by taking different samples of the same ore, the proper fineness having been previously determined. Three experiments will suffice to give a good idea as to the amount of heat to use. The first experiment should be conducted at a low heat from the start, gradually increasing to a light red at the end; the second started at a moderate heat, gradually increasing to a light red at the end; the third started at a light red heat, and kept so throughout. The time required for the three roastings should be the same—about two hours—to make sure that the first sample is thoroughly roasted. After roasting, each of the samples should be weighed, and the loss in weight noted, then assays made to determine the loss in gold, if any, by volatilisation. The samples are then chlorinated and tailings assayed. If no loss of gold has occurred by increasing the temperature at the start, and the extraction was equally good, then there is just one more point to be determined, the time required for the roasting. Five samples are taken and roasted, respectively, for one-quarter, one-half, one, one and one-half, and two hours. The

roasted samples are then again assayed for loss of gold by volatilisation, chlorinated, tailings assayed, and results compared.

The results obtained will have now shown the proper fineness required in crushing, and the best method of roasting (if oxidising roasting has been successful).

There is one more factor to be determined, the least amount of chemicals required. It is a very difficult matter to decide accurately on so small a scale as a laboratory experiment, since the actual condition of the working scale is not easily obtained with small quantities of ore. Indeed in actual working the consumption of chemicals seems to depend to a considerable extent on the size of the charge of ore, the larger the charge the smaller being the consumption of chemicals per ton of ore. This may be accounted for by the fact that an excess of chlorine or bromine is always necessary, and this excess will treat three or four tons just as well as one.

*Treatment of Ores subjected to a Chloridising Roasting.*—Some ores, when given a perfect oxidising roasting cannot be successfully chlorinated, because they require too large an amount of chemicals to produce an excess of chlorine or bromine. This is due to the presence of certain oxides and sulphates of base metals in the ore, such as zinc, copper, calcium, magnesium, and others, absorbing the chlorine as fast as it is produced. When such is the case, the difficulty may be overcome by the addition of a certain percentage of salt in the roasting. The manner in which the salt is added depends upon the nature of the gold and other metals in the ore; but, as a rule, it is best to add it near the end of the roasting.

In a chloridising, as in an oxidising roasting, the same questions should be determined with regard to fineness of crushing, temperature of roasting, and time of exposure of ore in furnace, together with the amount of salt, and when and at what temperature to add it. In addition to the foregoing experiments it is always advisable, although not absolutely necessary, to make a quantitative analysis of each ore treated. In practical work, where large quantities of ore from the same mine are constantly being treated and the ore is of a uniform nature, a part of the average sample may be laid away each day until, at the end of a week or a month, when these samples can be carefully mixed and an analysis of the resulting sample made. Where a number of different ores are continually being treated, a comparison of these analyses, with chemicals used and results obtained, could not fail to be of great interest.

The foregoing looks like a formidable mass of work to be expended on any one sample, but it must be remembered that the ore from any one mine, and frequently from one district, acts in a very similar way with any definite metallurgical process, and when such problems are once satisfactorily solved, they will cause very little trouble thereafter.

The practical operations in the mill may be conducted in several different ways, but in this paper reference is made only to the improved system of barrel chlorination.

In the case of ores not suitable for concentration where chlorination must be applied directly to the ore either in the raw or roasted state, the obstacles are more difficult to overcome. Such ores are of common occurrence in many parts of this and other countries, but their successful treatment by chlorination has been rare. The most notable, and probably the only instance in this country where such success has been attained, is in the Black Hills, in South Dakota, where the Golden Reward Company has demonstrated that the process is a practical one.

The ore, after being crushed, is roasted in Bruckner and Howell-White furnaces. After it is roasted the ore is charged into lead-lined barrels, having a capacity of from four to five tons of ore, where a sufficient quantity of bleaching powder, acid, and water is added. The barrels are then revolved for about an hour and a half, at the end of which time the gold is supposed to be chloridised and dissolved. The barrel is then stopped and the gold solution removed from the ore by means of pressure, and a filter arranged inside of the barrel, the outlet of which is connected with a pipe leading to the precipitating

tanks, or, in some cases, to the slime-settling vats, where, after standing a sufficient length of time, the clear gold-bearing solution is decanted into the precipitating tanks.

The gold-bearing solution, containing a large amount of free chlorine, is then treated with  $\text{SO}_2$ , until all the free chlorine is destroyed; when this point has been reached, the  $\text{H}_2\text{S}$  is turned on and the gold precipitated. The precipitated gold sulphide is collected in filter-presses, dried, roasted, and the gold melted into bars. Such, in brief, is the process followed at present by the most successful chlorination mill in this country, where ore is chloridised without previous concentration. Five prominent features may be mentioned in the process, as described. They are: Crushing, roasting, chloridising, leaching, and precipitating. It seemed impossible to leach very fine ore by the system employed in the Golden Reward Mill. In 1888, while assistant to Mr. T. K. Rose, now of the Royal Mint, of London, the author experimented with the ores of the Black Hills district, and found it a comparatively easy matter to roast and chlorinate them when crushed sufficiently fine to 30-mesh. In January 1893 the writer was again called upon by the Black Hills Milling and Smelting Company to demonstrate, if possible, the cause of their inability to chlorinate the ore. Rolls were used to crush the ore, and screens of 10 meshes to the linear inch. The roasting was accomplished by means of Bruckner and Howell-White furnaces, two of each kind being in operation.

*The Chlorination of Gold Ores.* L. D. Godshall. Eng. and Mining J. 1894, 32—33.

THE Rapid City works used bromine almost altogether, instead of chlorine. The author has recently been informed that bromine can now be obtained in quantity for as little as 18 cents per pound; ore well roasted should not require more than  $1\frac{1}{2}$  lb. of bromine per ton of ore; in fact, considerably less than this was used at Rapid City at times; whereas with chlorine it takes an exceptionally well roasted ore to bring the cost to 50 cents per ton of ore, taking western prices of chemicals as a basis.

That it is possible to extract a very high percentage of the gold from the refractory ores of the Black Hills by means of either chlorine or bromine when such ores are crushed to pass only an 8 or 10-mesh screen, is extremely doubtful, but with fine crushing it becomes at once simple and practical. The only difficulty yet remaining is the crushing. To crush a hard ore in the dry state so as to pass through a 30-mesh screen is a difficult thing to accomplish by means of rolls, while pulverisers of all kinds are still more to be dreaded.

The most practical and at the same time the most economical method of fine dry crushing is, in the opinion of the writer, by stamps. The desirability of using stamps instead of rolls will unquestionably be contrary to the convictions of many engineers. The writer, however, has seen and heard of so many breakdowns and so much trouble in mills where rolls were used, that the conviction has been forced upon him that stamps, notwithstanding their increased initial cost, and power required, are more reliable and more economical. An objection frequently brought against the use of stamps is the fact that a great part of the ore is crushed very fine and apt to produce slimes, but where pressure leaching is used these slimes are of no serious consequence. In fact, with many ores the finer the crushing the higher the extraction, and pulverisation rather than granulation should be the aim.

The furnace best adapted for roasting such fine ore depends somewhat upon the character of the ore; if very low in sulphur, the Howell-White will answer, although large dust chambers should be provided with this furnace. Much of the flue dust would also have to be roasted a second time. The Bruckner cylinder is better adapted for ores in general than the Howell-White, as the charges can be controlled better in this furnace, while the amount of flue dust produced is comparatively small. The Pearce turret furnace is good for ores moderately low in sulphur. This furnace has the good points of the old-fashioned reverberatory, and is mechanical in every respect, producing

also a comparatively small amount of flue dust. For concentrates or such ores as are high in sulphur or where a chloridising roasting is desired at the end the Pearce turret may answer, but a reverberatory or a mechanical furnace in conjunction with a reverberatory is to be preferred.

Where an ore contains iron pyrites or where the gold is associated with a hydrated oxide, as in the Victor mine, roasting becomes necessary. It is a curious fact that not a single ore was found in the camp that would not yield readily either in the raw or roasted state to the process of chlorination. However, the majority of the ores of the camp contain more or less tellurium combined with the gold, making the roasting a more delicate operation than it would otherwise be.

Various figures have been given as to the actual cost of treating a ton of ore by this process. The cost of treatment by this process, or any other, depends on a variety of circumstances, such as the price of labour, fuel, freight, capacity of mill, &c.

Estimate of the cost of treatment per ton by barrel chlorination based on Colorado prices, treating 100 tons of ore per day of 24 hours. The labour required is: 6 men unloading ore and fuel at 2 dols., 12 dols.; 5 men tramming ore and fuel at 2 dols., 10 dols.; 2 engineers at 3.50 dols., 7 dols.; 2 firemen at 2.50 dols., 5 dols.; 2 millmen at 3.50 dols., 7 dols.; 1 oiler, 2 dols.; 2 men at Blake crusher, at 2 dols., 4 dols.; 1 blacksmith, 3.50 dols.; 1 carpenter, 3 dols.; 1 machinist, 3.50 dols.; 1 helper, 2 dols.; 2 men at chlorinating barrels, at 3 dols., 6 dols.; 2 helpers at 2 dols., 4 dols.; 6 roasters at 3 dols., 18 dols.; 6 wheelers at 2 dols., 12 dols.; 2 foremen at 4 dols., 8 dols.; 1 clerk, 3.50 dols.; 1 assayer, 4 dols.; 1 helper, 1.50 dols.; 2 extra men for odd jobs at 2 dols., 4 dols.; 1 superintendent, 10 dols. The total cost will be as follows:—

	Total.	Per Ton.
Labour.....	Dols. 130	Dols. 1.30
Fuel.....	100	1.00
Repairs and supplies.....	50	0.50
Chemicals and assay office supplies.....	75	0.75
Or total cost of treatment per day..	355	3.55

For a plant to treat 25 tons per day of 24 hours, 26 men would be needed, and the cost would be:—

	Total.	Per Ton.
Labour.....	Dols. 75	Dols. 3.00
Fuel.....	40	1.60
Chemicals and assay supplies.....	25	1.00
Repairs and mill supplies.....	25	1.00
Total.....	165	6.60

In both of the above calculations the estimates are high, and should be considerably lowered in actual practice by having discharging waggons; for instance, the cost of unloading is practically done away with. If bromine can be used the cost of chemicals will also be much less, and this item should even be considerably less when chlorine is used. It was thought better to state the costs a little too high than too low. The greatest economy in milling ores by this process or by any other, lies in running the mill to its utmost capacity. It is impossible, as may be seen by the above figures, to treat ore in a 25-ton mill as cheaply as in one treating 100 tons daily, but it is still far worse to build a 100-ton mill and treat only 25 tons a day in it. Under such circumstances the cost of milling

may run up to 8 dols. or 10 dols. a ton. With most ores a minimum net extraction of 90 per cent. can be obtained by this process, but on low-grade ores it is safer to calculate upon a minimum net extraction of 85 per cent. of the gold contents of the ore.

*The Estimation of Phosphorus in Steel containing Silicon, and in Pig-iron.* J. Spüller and S. Kalman. Zeits. Anal. Chem. 32, 1893, 538.

See under XXIII., page 175.

#### PATENTS.

*Improved Process for the Manufacture of Litharge, Red Lead, and Cement from Galena or other Lead Ores, or from Sulphate of Lead.* W. S. Kilpatrick, Glasgow. Eng. Pat. 23,548, December 21, 1892.

THE galena or other lead ore is roasted or sublimed so as to form a mixture of sulphate and oxide of lead. This mixture, or the sulphate itself, is mixed with the necessary proportion of oxide or carbonate of the alkalis or alkaline earths or any other metal, and is calcined in a reverberatory furnace till the mass consists of lead oxide. The sulphate is then removed by grinding and washing if litharge is required, or allowed to remain for cement, and the litharge may be converted into red lead by the ordinary process. Oxygen may be used at any stage of the process if desired.

—F. H. L.

*Coating or Covering Paper with Aluminium.* W. Ibbotson, London. Eng. Pat. 23,603, December 22, 1892.

See under XIX., page 170.

*An Improved Process for the Manufacture of Aluminium Sulphide.* C. T. J. Vautin, London. Eng. Pat. 751, January 12, 1893.

METALLIC aluminium is melted in proper proportions with lead or other suitable metallic sulphide at a bright red heat in a neutral atmosphere, in a crucible or reverberatory furnace with basic lining, and preferably gas-fired.—J. H. C.

*Improved Means for Producing Crucibles or Melting Pots.* E. J. T. Digby, Liverpool. Eng. Pat. 3661, February 18, 1893.

THE materials used are as follows:—

	Parts.
Plumbago, in 17-mesh granules .....	17
"      in 80-mesh " .....	2
Russian clay .....	5
China stone .....	5
Gas carbon .....	2

The three last are separately ground to a fine powder; the others are then added in a suitable mixing machine and kneaded together with a little water. The vessels are then formed, dried at 150° F., and finally baked in a kiln.

—J. H. C.

*Improvements in or relating to Apparatus for Galvanising Sheet Metal.* J. V. Lagnesse, Grevegué, Belgium. Eng. Pat. 4298, February 27, 1893.

THE apparatus consists of two frames provided with hooks, connected with and by rods or links, and so arranged that they can be operated at a distance from the galvanising bath. One of these serves for immersing the plate and the other for withdrawing it and causing it to pass through sand without necessitating the use of rollers or other like appliances.—J. H. C.

*Improvements in the Manufacture of Metallic Oxides and Compounds.* E. de Pass, London. From H. Thofehn, Paris. Eng. Pat. 10,096, May 20, 1893.

THE metals to be oxidised are melted and made to flow in a thin stream through blasts or jets of steam, gas, air, water, acids, or other suitable reagents, which have been previously heated, if necessary. In this way the metals are pulverised or sprayed into little drops or particles, none of which can escape the action of the reagent employed. Illustrations are given of the form of apparatus recommended by the inventor.—J. H. C.

*Process for Avoiding or Considerably Diminishing the Choking and Contraction of the Mouth of the Retort in the Manufacture of the "Thomson" Steel.* A. Raze, Ongrée, Liege. Eng. Pat. 16,857, September 7, 1893.

A NUMBER of openings are formed around the mouth of the retort, and immediately above the level of the molten metal. Through these openings air is blown during the operation of conversion or casting, so as to obtain a more perfect combustion of the matters which ordinarily condense around the mouth.—J. H. C.

*A New Process for Reducing Sulphuretted Ore into Oxides and Sulphur.* L. Bemelmans, Brussels. Eng. Pat. 19,606, October 18, 1893.

See under VII., page 153.

*A New or Improved Metallic Alloy.* J. Cox, Birmingham. Eng. Pat. 22,461, November 23, 1893.

THIS alloy has the appearance of silver, receives and retains a high polish, does not tarnish, can be rolled into sheets or drawn into wire, and is cheap to manufacture. It is composed of copper, nickel, spelter, antimony, tin, and lead, and is prepared as follows:—

Mixture number one is first prepared by melting 78 lb. of copper and adding first 20 lb. of nickel and then 12 lb. of spelter, 1 lb. of antimony, and 1 lb. of tin. 64 lb. of this mixture is then melted and 22 lb. of spelter, 2 lb. of tin, and 8 lb. of lead are added, thus forming the improved alloy.—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*A New Accumulator.* K. Lenz. Mitth. K. K. Tech. Gewerbe-Museums in Wien. 1894, 84—89.

THE author states that Sigmund Randnitz has constructed an accumulator in which neither pure lead nor pure lead oxides are primarily used as materials, but instead a lead compound the nature of which is kept secret. By charging, this becomes converted into a stone-like peroxide without buckling or altering in shape. The result is a large increase in capacity for a given weight. A cell of three plates (one +, two —) weighed 1.09 kilos. (each plate having a surface of 6 × 16.5 cm.), and had a capacity of 32.8 ampère-hours, or 30.1 per kilo.; the acid strength was 26—27 per cent. The advantages and disadvantages of the systems of Planté, Faure, Tommasi, Tudor, and Randnitz are thus contrasted, the capacities being stated in ampère-hours per kilo. of plates.

*Planté.*—Requires a long period for formation; plates separated by intermediate filamentous layer. Capacity, 3—4.

*Faure.*—Short period of formation. Porous intermediate layer to prevent erosion and breaking up of plates. Capacity, 10—15.

*Tommasi*.—Diminution of tendency to break up by introduction into perforated acid-proof frames. Capacity, 22·5.

*Tudor*.—Production of stable active plates from massive lead plates. Capacity, 3·5—4.

*Randnitz*.—Unalterability, cheap renewal, large capacity. Capacity, 30·1.—C. R. A. W.

*New Apparatus for the Manufacture of the Metals of the Alkalis and Alkaline Earths by Electrolysis.* W. Borchers. *Zeits. f. ang. Chem.* 1893, 16, 486—489.

In the construction of apparatus for the manufacture of the alkali metals by the electrolysis of the fused haloid salts of the latter, the following rules must be observed:—1. The alkali metal must be deposited at a metallic (iron) kathode. 2. The kathode space must permit of the collection and removal of the metal without the latter coming into contact with reducible substances. 3. The anode must be of carbon. 4. The anode space must permit of the ready removal of the halogen, and its walls must be constructed of material capable of withstanding the action of halogens and haloid salts. 5. No metallic particles should be present in the melt between the poles. 6. All the parts of the apparatus must be constructed of fire-resisting material.

These conditions are partially fulfilled by Grabau's apparatus (1889), and also by an apparatus described by the author in 1891. The whole of the difficulties have only been surmounted, however, by the construction of the apparatus shown in Figs. 1. and 2. It consists of two

Fig. 1.

COOLING WATER INFLOW.

communicating vessels, of which one, the kathode space K, is of iron; the other, the anode space, is of chamotte. A jacket is furnished for the anode a, by means of which no chlorine can reach the kathode, and the outside of which is out of contact with the melt and with the strongly reducing alkali metals. The employment of a tubular kathode for the collection and discharge of the metal is also possible, on the inner side only of which the metal can be deposited, as the outer side does not as a rule come into contact with electrolytes. The two vessels are bound together by a hollow metallic band R and two clamps Z above and below it; a stream of water passed through the hollow band, locally solidifies the melt, which effects the luting. The

flange between the vessel A and the band R is packed with asbestos, which acts as a damper in order to prevent cracking. A tube C serves to lead off the halogen. Dropping the salt directly into the anode vessel is apt to cause the latter to crack; the salt is therefore introduced in small lumps through S, the bottom of which is covered with a layer of asbestos.

Fig. 2.

The current density at the kathode should be about 5,000 ampères per square metre. An advantage of the new apparatus is that with a current density remaining constant at the kathode, the current density at the anode may be reduced, which means a great saving of energy.

The electrolytic preparation of the alkaline-earth metals presents many more difficulties than that of the alkali metals. The mixtures of salts melt only at a red heat, and the metals themselves at still higher temperatures. The melting point of barium, for example, is near to that of iron; then follows strontium, calcium having the lowest melting point of the three.

A current density at the kathode of 1,000,000 ampères per square metre is necessary. Fig. 3. shows an improved

Fig. 3.

apparatus for this purpose. A wrought-iron crucible T serves for the decomposition vessel; a U-shaped piece of sheet iron is inserted into it at U, and below this pins K which serve as kathode, are screwed into the walls of the

vessel. The size of the pins is so regulated that during the electrolysis there shall be a current density of one ampère per square mm. of exposed surface. A strong bar of carbon A serves for the anode, or a bundle of thin rods or plates of the same material; a tube C is furnished to lead off the halogen.

The *modus operandi* is as follows:—The fused haloid salts of the alkaline-earth metals are poured into a cold crucible, the heated bar of carbon immediately dipped into the melt, and connected with the current. The walls of the crucible are covered with a crust of the solidified melt, which isolates them completely; this is therefore maintained during the operation by cooling either by air or by water. The crust is only quickly re-melted at the kathode. The resistance of the melt must be great enough that the current causes a sufficiently strong heating to keep the electrolyte molten. In consequence of the great current density at the kathode, this is heated far above the surrounding temperature. The metal here deposited may agglomerate to a molten mass, which falls or rises, and finally solidifies under U. The great current density causes much of the metal to be swept into the anode space, where, naturally, it is oxidised; a portion of the metal, after dropping from the kathode, is also dissolved by the haloid salts, forming basic compounds. The highest yield of metal realised is 20 per cent. of the theoretical; this, however, shows a great advance, for with the arrangements at hand heretofore only a 5 per cent. yield is attainable.—A. R. L.

#### PATENTS.

*New or Improved Treatment of Hydrocarbons (or of Analogous Substances Composed mainly of Hydrogen and Carbon) to Decompose them and Obtain Various Products.* W. J. Wisse and A. Schneller, The Hague, Holland. Eng. Pat. 21,343, November 23, 1892.

ACCORDING to this invention, hydrocarbon oils, such as kerosine oil or its residue, are split up electrically in a closed iron vessel in which are immersed electrodes supplied with electrical energy of high electromotive force—about 30,000 volts—from an alternating current transformer, or high potential continuous currents may be employed; the oil undergoing decomposition with deposition of carbon, which it is proposed to collect for the manufacture of lampblack by subsiding or filtration. Other products are collected from the oil so treated, some better adapted for lubricating purposes than the original oil; these, as well as the vapours escaping from the vessel, containing anthracene and other products, may be collected and separated by distillation. The inventor proposes to treat resin, tar, bitumen, vegetable oils, fats, alcohols, &c., to obtain lampblack and by-products analogous to those obtained in the treatment of mineral oil.

—J. C. R.

*New or Improved Galvanic Batteries.* C. A. J. H. Schroeder and H. E. R. Schroeder, England. Eng. Pat. 23,101b, December 15, 1892.

EACH cell of these primary batteries consists of a chamber divided by a porous partition into two compartments, each supplied by two tubes with different mixtures of gases. Each compartment contains two platinum conductors, which, on being heated and brought into contact with each other, cause a chemical combination of the gases in the different compartments, and generate an electric current. The porous partition may be replaced by a flat porous pot filled with a conductive liquid, such as dilute sulphuric acid, &c. In battery No. 2 the outward application of heat is employed, and two single gases are used instead of two gas mixtures. The galvanic action in battery No. 3 depends on one liquid being an electro-positive element dissolved in a conductive liquid, and the other an electro-negative element also dissolved in a conductive liquid. To dissolve these substances an alteration of temperature is required in some cases, and a high pressure in others. The positive liquid in

this battery may be replaced by immersing amalgamated zinc or one of the alloys given in Eng. Pat. 22,956, 1893, in dilute sulphuric, hydrochloric, or nitric acid.—G. H. R.

*Improvements in Electric Smelting and in Furnaces therefor.* R. Niewerth, Berlin, Germany. Eng. Pat. 23,773, December 24, 1892.

THESE improvements relate to the construction of an airtight electric furnace, with electrodes passing through stuffing boxes at the top of the furnace, the cathode being at the bottom, and shown as a flooring to be in contact with the metal to be smelted, for which arrangement advantages are set forth.

The smelting is proposed to be effected by an electric arc or arcs out of contact with air, to avoid oxidation, which is said to render electric smelting expensive. Inlet and outlet pipes are provided for gases, with a hopper with water or other seal at the top of the furnace to supply fresh material. In the case of removing carbon from aluminium and iron, it is proposed to conduct the operation in the presence of hydrogen, which will remove the carbon as hydrocarbon gases, and assist the action of fusion.

When smelting copper, it is proposed to introduce carbon monoxide into the furnace to avoid oxidation, and if oxides are present as impurities reducing gases are admitted.

—J. C. R.

*Improvements in Electrolytic Apparatus.* E. Andreoli, Brixton, Surrey. Eng. Pat. 1661, January 25, 1893.

THIS invention (relating to further improvements on Eng. Pat. 18,597, 1891) refers to the employment of what is termed a conducting diaphragm, constituting a cathode, but only taking a small proportion of the whole current passing through the electrolyte, which is mainly carried by a separate cathode, between which and the anode the diaphragm is placed. This diaphragm is constructed of gauze and granular conducting material, which is protected from corrosion by the slight electrolytic action taking place upon it while the electrolysis current is passing, and when disconnected from that source of supply, to attain the same object, it may be joined up with a primary or secondary battery in the same manner.

Apparatus is described for the electrolytic production of chlorine and caustic soda, employing an anode of carbon and a cathode of iron; circulating and cooling the electrolyte, and decomposing hypochlorites in the anode compartments by acids or salts, being also referred to.—J. C. R.

*A New Galvanic Battery.* C. A. J. H. Schroeder and H. E. R. Schroeder, Balham, Surrey. Eng. Pat. 2241, February 1, 1893.

A BOLT of slate, porcelain, agate, or other suitable material is provided at each end with threads, lubricated with black lead; on one end of the bolt is screwed a nut of the same or of either of the above-mentioned materials. The bolt is then reversed in position, and an amalgamated zinc plate is threaded on it. This is followed by a plate of vulcanite, slate, or other suitable insulating material, which in its turn is followed by a carbon plate, a zinc plate, an insulator, and so on alternately until the last plate is in position, when they are firmly pressed together, and held in place by a second nut screwed on the other end of the bolt. The complete battery cell when in use is placed in a suitable receptacle of such shape that the cell fits closely in one direction, while a free space is preferably left at each side in the other. If the battery is required for continued action a reservoir is attached to it. The solution used may consist of any suitable exciting liquid, such as bichromate of potash, or that described in Eng. Pat. 23,101, 1892.—G. H. R.

*A Manufacture of Pharmaceutical Preparations, for Use more particularly in Cases of Anæmia and for Weak Throats.* W. Webster and T. Moore, Blackheath, Kent. Eng. Pat. 2884, February 9, 1893.

THIS invention relates to the production of weak solutions of iron, for pharmaceutical preparations, by placing electrodes of iron, to which battery connections are made, in an electrolyte of a weak solution of common salt, thereby obtaining by electrolysis oxides and carbonates in solution, which may be under pressure of carbon dioxide generated within the vessel, or separately treated with that gas to form aerated chalybeate water. An apparatus is shown in which the cathode of iron forms the lower part of the containing vessel, and an iron pipe the anode, which also answers for leading out the solution, as in a seltzogene, and can be renewed. The carbon dioxide is generated in a glass chamber fixed on to the top of the iron cathode. Glycerin may be added to the solution to prevent oxidation of the neutral salt of iron, and to reduce its astringent properties for internal use; and where carbon dioxide is applied direct to the electrolyte, common salt may be dispensed with.

—J. C. R.

*Improvements in Secondary Battery Plates or Elements.* A. Hough and O. March, London. Eng. Pat. 3731, February 20, 1893.

ACCORDING to this improvement the lead peroxide plates for secondary batteries are formed by filling the support with lead oxide mixed in a dry state with some suitable setting salt. The supports are of lead or lead alloy, either in the form of grids, or of troughs or channels, and are constructed in such a way as to yield without injury or distortion to the expansion of the active material which takes place during formation.—G. H. R.

*Improvements in the Preparation of Carbon Electrodes for Electrolytic Operations.* E. H. Liveing, London. Eng. Pat. 3743, February 20, 1893.

THE object of this invention is the removal of the undecomposed hydrocarbons from the retort carbon, before the latter is used as an electrode, so as to obviate the objections which may arise from their presence. This is effected by subjecting the carbon to a high temperature in a current or atmosphere of chlorine gas.—G. H. R.

*Improvements in the Construction of Carbon Electrodes.* E. H. Liveing, London. Eng. Pat. 3741, February 20, 1893.

WITH the object of overcoming the difficulties occasioned by the electrolysis of the chlorides of sodium and potassium, the inventor makes the following arrangement:—Broken pieces of gas-retort carbon are placed on a sieve, grid, or series of bars of slate or other non-conducting material. Electrical communication is made with the anode chamber, which is closed at the top by means of carbon rods or protected metallic conductors passing through stuffing boxes in its cover, and making contact with the carbon on the grid; and as the carbon rods will also waste at their ends they are made to slide through the stuffing boxes by means of a spring or weights. The number of rods necessary for a cell will be determined by the amount of current required.

—G. H. R.

*Improvements in the Construction of Plates for Accumulators or Secondary Batteries.* W. P. Thompson, London. From La Société Electric Phœbus, Paris, France. Eng. Pat. 4360, February 28, 1893.

ACCORDING to this improved method of construction the plates are cast with two or more grated faces held apart, and rendered solid by means of cross pieces, which are also cast at the same time with the plates, forming a grate, which, it is claimed, possesses great mechanical solidity. The plate, formed preferably of antimoniated lead, presents,

as a whole, two grated parallel walls provided with cross pieces on a median vertical line, and three horizontal ones. The positive and negative plates are separated from each other by means of any suitable insulating material placed in holes in them, and projecting beyond them, maintaining them at a suitable distance apart. G. H. R.

*Improvements in Electric Accumulators.* F. W. Ellermann, Vienna, Austria. Eng. Pat. 8952, May 1, 1893.

ACCORDING to this improvement the active porous material (preferably oxides of lead, such as litharge or peroxide of lead) is applied in a comparatively thick layer, the individual particles of which are connected electrically by means of mercury so as to reduce the resistance; while for the purpose of avoiding too rapid a discharge a finely-divided electrolytically inert body is added to the mass. The mercury compound added is the sulphate, which becomes reduced, and thus mercury becomes disseminated through the mass. The improved active mass is composed as follows:—

For the positive mass:

	Parts
Peroxide of lead.....	100
Sulphate of sodium.....	10
Sulphate of magnesium.....	5
Peroxide of manganese.....	3

For the negative mass:

	Parts
Litharge.....	100
Sulphate of sodium.....	10
Sulphate of magnesium.....	5
Sulphate of mercury.....	3

—G. H. R.

*Improvements in the Manufacture of Ammonia, Sodium Hydroxide, and Chlorine, and in Apparatus therefor.* C. Kellner, Vienna. Eng. Pat. 13,722, July 14, 1893.

See under VII., page 152.

*Apparatus for the Electrolytic Production of Bleaching Liquid.* C. Kellner, Vienna, Austria. Eng. Pat. 13,723, July 14, 1893.

THIS apparatus relates to a plan of constructing electrolytic apparatus for the production of hypochlorite of soda from a solution of common salt, by arranging a series of electrodes in a containing tank in such manner that their opposite sides act as different electrodes, but all contained in the same electrolyte, which circulates round their ends, taking a zig-zag course by spaces left for the purpose at the end of each alternate electrode. The electrolyte is supposed to undergo electrolysis on the opposite side of each electrode rather than travel by way of the passage of electrolyte around the ends of the electrodes from one extreme plate to the other, to which, only, terminal connection is made. Where carbon is used as electrodes, it is proposed to introduce a filter of glass wool between the decomposing apparatus and bleaching reservoir.—J. C. R.

*Improvements in the Method of and Apparatus for Electrically Heating or Working Metal or other Materials capable of Momentarily Withstanding the Heat of an Electric Arc.* W. P. Thompson, Liverpool. From C. L. Coffin, Detroit, State of Michigan, U.S.A. Eng. Pat. 18,990, October 10, 1893.

THIS invention consists essentially in acting upon the electric arc produced between electrodes by an electromagnet in such manner as to attract or repel the arc, and so cause it to play upon a larger area of the material being heated, than if permitted to concentrate its heat upon one point, it being rapidly moved from one point to another by the influence of the magnet, whereby an arc of greater power may be used than if it were stationary, and a correspondingly greater effect produced. Apparatus is described

and shown for carrying out this method, which is said to be applicable for heating other materials than metals, such as glassy sticite, or other silicious or boracious compounds in which it may be desired to produce incipient fusion.

—J. C. R.

*Improvements in Apparatus for the Electrolytical Decomposition of Salt Solutions.* C. Kellner, Vienna, Austria. Eng. Pat. 19,542, October 17, 1893.

This apparatus is for bleaching paper pulp or textile fabrics, and is termed a bleaching block. A number of plates are bound together, but insulated from each other, so as to act as electrodes in series, terminal connection being made to the end plates only. These blocks are immersed in the solution to be electrolysed, as common salt, for the production of hypochlorite of soda, and are shown for use in an ordinary rag engine containing paper pulp, and for bleaching textile fabrics. For the surfaces of the plates making up the block, the anode surface is of platinum foil, and the other, or cathode side, amalgamated with mercury, the plates being of sheet copper, tombac, or phosphor bronze. The apparatus being worked in the presence of the material to be bleached, which passes between the plates, economy is claimed.—J. C. R.

*Production of Ozone and Luminosity by Electrical Means.* E. Andreoli, Brixton, Surrey. Eng. Pat. 21,707, November 14, 1893.

This invention relates to the production of ozone and luminosity, by placing in a vacuum tube of glass, or other dielectric vessels, an electrode consisting of a carbon filament or a metallic wire or wires radiating towards the inner side of the glass tubes; and outside the tube, and in proximity to it, is fixed the other electrode, having points directed towards the centre of the tube. These electrodes being connected up with a Ruhmkorff coil or high frequency transformer, as soon as the current passes the inside of the tube becomes luminous; at the same time on each of the points of the electrodes the characteristic glow of the silent discharge appears, and is accompanied by a strong smell of ozone. It may be understood (although not stated) that the apparatus is worked in atmospheric air or oxygen. Eng. Pats. are referred to: 17,426 of 1891, 9631 of 1892, and 21,794 of 1892; this Journal, 1893, 452.—J. C. R.

*Improvements relating to Storage Batteries.* E. P. Usher, Massachusetts, U.S.A. Eng. Pat. 22,311, November 21, 1893.

The inventor describes an improved battery plate constructed of a frame having upright bars or arms vertically grooved in their outer faces, and formed with edgewise flanges extending into the space between the bars, in combination with non-conducting separators in contact with the opposite faces of the frame, and with a filling of material adapted to become active in the spaces. The plates and interposed separators are set in a shallow body of cement or gum, the several plates being supported at a slight distance above the bottom of the vessel containing the gum.—G. H. R.

*Improvements in Storage Batteries.* E. P. Usher, Massachusetts, U.S.A. Eng. Pat. 22,312, November 21, 1893.

In this battery the plates are formed of lead sheets separated by sheets of wood, earthenware, or any equivalent porous substance, and rest in spaces or end pieces provided with a slot their whole length to receive the edge of the lead sheet, and preferably having the sides which come against the surface of the separator sheet fluted or corrugated, which allows of the circulation of the acid. The cell is built up of several of these sets, and when put together the entire cell is placed in a shallow pan filled to the depth of a quarter or a third of an inch with hot, liquid gum, which sets hard when cold. The several chambers between the separators which contain the lead plates are filled with lead oxide.—G. H. R.

*Improvements in the Manufacture of Incandescent Bodies for Incandescent Gas Lighting.* R. Langhans, Berlin, Germany. Eng. Pat. 22,396, November 22, 1893.

See under 11., page 141.

*Improvements in Disinfecting.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 18,370, December 16, 1893.

See under XVIII. (C.), page 170.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Valuation of Tallow by Determination of the Solidification Point of its Fatty Acids.* F. Wolfbauer. Mitth. k. k. Tech. Gewerbe-Museums in Wien, 1894, 57.

See under XXIII., page 181.

### PATENTS.

*An Improved Furnace Pan and Concentrator for the Boiling of Fish Livers and the like.* C. B. Lotherington and I. Spencer, Hull. Eng. Pat. 23,542, December 21, 1892.

DESCRIPTIONS and drawings are given of a closed, flat-bottomed pan with sloping sides, and fitted with an agitator. An outlet pipe carries off the noxious vapours evolved. This outlet pipe is connected (outside the pan) with a pipe with rose, through which water may be admitted in sprays, which condenses part of the vapours en route to the fireplace, whilst the rest are drawn to the ash-pit and the fire, and thus consumed. A suitable drain pipe passing vertically downwards to the drains, carries away any condensed water, &c., collecting in the lower part of the pipe from pan to fireplace, as it forms an elbow in bending round and proceeding horizontally to the grate of the fireplace.

—K. E. M.

*Improvements in and connected with the Separation of Cholesterin and Fatty Acids from Wool Fats.* L. Krause and J. Mayer, Wittenberg. Eng. Pat. 20,639, November 1, 1893.

The cholesterin and fatty acids contained in raw wool-grease are separated by distillation, for which purpose superheated steam or better still, direct heat is applied. The distillation is continued until the distillate, consisting of a yellow granular mass composed chiefly of fatty acids, begins to show a brown tint. The residuum is a black-brown product, consisting mainly of cholesterin.—K. E. M.

## XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

### (A.)—PIGMENTS, PAINTS.

#### PATENTS.

*An Improved or New Manufacture of Black Lead.* R. Ripley, Liverpool. Eng. Pat. 23,206, December 16, 1892.

To obviate the necessity for the large amount of friction required to give a polish to black lead when used in the

ordinary way, the inventor prepares a kind of paint consisting of black lead, beeswax, and turpentine in varying proportions, of which the following may be taken as the average:—1 part of wax, 2 of turpentine, and 24 of plumbago. The turpentine is replaceable by petroleum spirit, and the beeswax by any other wax which will give a similar polish.—F. H. L.

*Improvements in Apparatus employed in the Manufacture of White Lead.* J. V. Walton, Bollisheope, near Darlington. Eng. Pat. 3116, February 11, 1893.

This patent refers to the manufacture of white lead by the Dutch method, and has for its object to reduce to a minimum the handling of the product during some of the different processes involved. The stack is a brick building containing tiers of tank girders of L-section, the flanges of which act both as rails for the passage of the loading and unloading trucks, and also as supports for the perforated grids on which the pots of lead and acid stand. The webs of the girders are of such a height, that they project above the pots when *in situ*, so that on them may be laid a layer of flooring boards to carry the tan. On the outside of the building, corresponding with each pair of girders is provided a hinged platform supported by movable brackets, which, when erected, forms a continuation of the rails for the trucks. These trucks are provided underneath with hooks and lifting gear, so that they may carry the grids to their appointed place, drop them, and return to the outside platform, there to receive a fresh grid and pots raised from the ground by a crane. Doors are provided to close the different apertures, as well as skylights, sight-holes, ventilators, &c. On completion of the reaction, the stack is uncharged in a similar manner, the white lead removed from the pots and taken to the grinding mills and treated as usual. The drying stove consists of a building somewhat similar in design to the stack, having tiers of angle irons or ledges on the sides to carry the trays; on the floor is laid a line of rails for a truck, which has a platform raised by a long screw, so that the trays, when placed on the truck, may be made to coincide with any of the different shelves. In the drawings is shown a stove of two storeys, each with its line of rails, and two trucks of different heights are provided in case the one has not sufficient lift to reach every shelf.

—F. H. L.

*Improvements in Apparatus employed in the Manufacture of White Lead.* J. V. Walton, Darlington. Eng. Pat. 16,703, September 3, 1893. (Compare preceding abstract.)

This patent is the complement of the preceding one, also having for its object the avoidance of manual labour during the processes of grinding and packing the white lead made by the Dutch method. The white lead is transferred from the converting pots by means of suitable tools to boxes fixed on the floor of tipping trucks, which are run into the grinding shed. This is as far as possible an air-tight building, lighted from the sides and top and provided with a ventilating fan. The truck is tipped by gear actuated from outside the building over the mouth of a hopper, into which water is sprayed, communicating with the grinding rollers. After grinding and drying, the material is emptied into boxes fixed on exactly similar trucks and run into the packing room. This resembles the grinding shed, being air-tight and having its fan, and the trucks are tipped as before over a hopper fitted with a regulating slide, also worked from the outside. Doors are provided at opposite sides, through which the trucks carrying the casks are introduced and withdrawn. While charging, the cask is lifted off the truck by a counterweighted lever and hooks, to which a revolving toothed wheel gives a rapid succession of blows so applied as to lift it up and let it drop 20 or 30 times per minute, whereby the white lead is thoroughly consolidated without having recourse to the hand labour usually employed in packing.—F. H. L.

*Improvements in the Manufacture of Oxide of Iron, and in Means applicable for use in such Manufacture.* H. W. Hemingway, London. Eng. Pat. 4001, February 23, 1893.

In the ordinary processes for the manufacture of oxide pigments ("Venetian red," &c.) the crude ferrous sulphate is ground to powder before furnacing, which results in its becoming locally overheated and consequently spoilt in colour. To avoid this, the inventor, after evaporating down the copperas liquor, casts the sulphate into rectangular blocks of a size and shape corresponding with the retorts in which it is ignited. A convenient size is 12 inches in diameter and 1 inches thick, and they may advantageously be cast round a hook- or eye-ended metal bar to aid in their manipulation. The furnace for burning them consists of a number of vertical chambers, the alternate ones being filled with the blocks, while the furnace gases circulate in the others. The former are provided with a lid at the top to introduce the sulphate, and a hinged door at the bottom to allow the finished oxide to fall through on to barrows or other receptacles when opened. This device renders the process continuous and does away with the cooling of the furnace, to which the usual conduits for the removal of the acid fumes are attached near the top of each of the vertical retorts.—F. H. L.

*Improvements in and relating to the Manufacture of Paints, Sulphuric and Sulphurous Acid from Proto-sulphate of Iron.* M. N. D'Andria, Stretford, Lancaster. Eng. Pat. 4342, February 28, 1893.

THE ferrous sulphate is heated in retorts in the usual manner, the evolved gases being made to pass into a sulphuric acid chamber which is at work in the ordinary way. The anhydrous sulphuric acid is at once absorbed by the chamber acid, strengthening it, and thus materially reducing the cost of the subsequent concentration. As an alternative arrangement, the pipes leading from the retorts may be made to condense the sulphuric acid, and the remaining sulphurous oxide either led into the chamber to be oxidised as before by the nitrous gas or used for the manufacture of sulphurous acid or sulphites.—F. H. L.

*An Improved Paint.* E. Edwards, London. From J. W. Overton, Louisville, U.S.A. Eng. Pat. 9825, May 16, 1893.

This paint, which is said to be specially suitable for painting ships' bottoms, being unaffected by salt water, is prepared by grinding rutille (titanium dioxide) with coal-tar, bitumen, "or other hydrocarbon of the like kind." Any other compound of titanium may be used if preferred, and the proportions may vary from equal parts to  $3\frac{1}{2}$  parts of the pigment to one of the vehicle.—F. H. L.

*Improvements in the Manufacture of White Lead.* E. Waller, New York. Eng. Pat. 22,294, November 21, 1893.

This patent refers to improvements in the use of ammonium acetate for decomposing litharge, massicot, or native lead carbonate. The ore containing lead in the latter form is heated in a still with a 10 per cent. solution of ammonium acetate, about 40 gallons being employed for every 100 lb. of lead in the material to be treated. The evolved vapours are condensed and form a solution of ammonium carbonate, which is added to the contents of the still after the insoluble substances have been filtered off. A precipitate of white lead is thus obtained, and the supernatant liquid, consisting of ammonium acetate, may be used over again with the next batch of ore. The precipitation should be carried out at a high temperature, so that the product may be as fine as possible. If the ore contain copper or silver, metallic lead should be added in quantity sufficient to replace them, and they may be recovered from the filter sludge.—F. H. L.

## (E.)--RESINS, VARNISHES.

## PATENTS.

*Improvements in or relating to Compounds of "Blown" or Aërated Oils with Pyroxylin.* I. S. Fairfax, London. From W. D. Field, Milburn, New Jersey, U.S.A. Eng. Pat. 3469, February 16, 1893.

By combining a blown non-drying oil, containing unsaturated fatty acids, with pyroxylin or nitrocellulose a compound is produced, which is proof against the action of water and atmosphere. It is suitable as a coating for textile fabrics, paper, and leather, also useful as an insulating material. Drying oils or those belonging to the linseed oil group are not suitable for this purpose, whilst those belonging to the cotton-seed oil and olive oil group are well adapted. The blown oil is prepared by aërating a suitable oil at a temperature of about 200° C. until it has obtained the required degree of viscosity. Before mixing the pyroxylin with the oil the nitrocellulose is dissolved in a liquid, which is also a solvent for the oil, and for this purpose a mixture of amylacetate and benzine (petroleum spirit) is recommended.—K. E. M.

*Improvements in and connected with Varnishing in Colours.* J. Perl, Berlin, Germany. Eng. Pat. 21,455, November 10, 1893.

THE articles to be varnished, metal, bone, celluloid, &c., are coated in the usual manner with colourless varnish, thoroughly dried, and then coloured. The colouring bath consists of a solution of a vegetable, aniline, or alizarin colouring matter in a strong alcohol, e.g., methyl, ethyl, or amyl alcohol, or in ethyl acetate, amyl acetate, or acetone. In this solution the articles are momentarily immersed, freed from excess of liquid by shaking or by centrifugal action, and finally dried at a gentle heat.—R. B. B.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Glycerin as an Agent for Softening Leather.* Papier Zeit. 1893, 18, 2280.

GLYCERIN imparts considerable suppleness to leather, but soon sweats out in damp air. To fix it in the leather, it should first be incorporated with four times its weight of the buttery mass made by dissolving beef fat in warm cod-oil. Another method of rendering the glycerin a permanent constituent of the leather is to incorporate it with a small proportion of white of egg; this mixture may be applied alone or may be followed by the above described glycerin-oil. A solution of dextrin may be substituted for white of egg if this latter be too costly. By dissolving a tan-stuff in glycerin and mixing it with cod-oil and fat, a valuable stuffing for leather may be obtained.—A. G. B.

*Cements for Leather Belting.* Papier Zeit. 18, 2618.

THE following are given as suitable cements for making joints in leather driving belts:—

1. Equal parts of good hide glue and American isinglass, softened in water for ten hours, and then boiled with pure tannin until the whole mass is sticky. The surfaces of the joint should be roughened and the cement applied hot.

2. 1 kilo. of finely-shredded gutta-percha digested over a water-bath with 10 kilos. of benzol until quite dissolved, when 2 kilos. of linseed-oil varnish are stirred in.

3. 1½ kilos. of finely-shredded india-rubber is completely dissolved in 10 kilos. of carbon bisulphide by heating. Whilst hot 1 kilo. of shellac and 1 kilo. of turpentine is added, and the solution heated until the two latter ingredients are also dissolved.

4. 1 kilo. of best glue is dissolved at a moderate heat in 1½ kilos. of water, and thickened to the consistency of syrup. 100 grms. of thick turpentine and 5 grms. of carbo-holic acid are carefully stirred in whilst hot. The mixture is poured into flat tin pans and allowed to cool, then cut into pieces and dried in the air. The cement is made liquid with a little vinegar and applied to the joint with a brush. The two ends of the joint are then placed together and pressed between two iron plates heated to about 30° C.

5. Gutta-percha is dissolved in a mixture of 5 kilos. of carbon bisulphide and 1½ kilos. of turpentine oil until the resulting mass has the consistency of porridge. The surfaces of the joint must be freed from grease before this cement is applied and the joint kept under pressure until the cement is dry.

6. 250 parts of gold size, 60 parts of isinglass, and 60 parts of gum arabic are boiled in a water-bath until a homogeneous mixture is formed; 5 parts of Venetian turpentine, 6 parts of turpentine oil, and 10 parts of spirits of wine are then added. The joint, after cementing, is pressed between hot plates and allowed to get quite cold before the pressure is removed.—R. B. P.

## PATENTS.

*A Process for Clarifying or Decolourising Tannic Extracts.* A. and H. Sinan, Nantes, France. Eng. Pat. 22,480, December 7, 1892.

BLOOD or other gelatinous or albuminous matter (1 litre) is mixed with bicarbonate of soda (1 kilo.) and water (½ litre) and the mixture boiled by injecting steam for one hour. This liquor is poured into the ooze (20°–30° B.) through a sieve, and mixed therewith by the arms of a rotating shaft. The ooze, which need not be heated, is allowed to stand until the colouring matters have been carried to the bottom.

The product thus obtained is said to satisfy all the requirements of the tanning process.—A. G. B.

*An Improved Process to make Leather Soft, Durable, and Waterproof.* W. Becker, London. Eng. Pat. 4274, February 27, 1893.

THE tanned hide is shaved to the required substance and slicked on the grain until every appearance of this "becomes invisible." The hide is then dried, stretched in a frame with the aid of a stretcher (moon) until the hide is thoroughly soft. A second slicking on the grain follows, and the same side is covered with train oil (free from resin) and laid on the table. The flesh is now scoured and greased with a solution of one-half degrass, one-quarter tallow, and one-quarter train oil, previously boiled and allowed to stand for a few days. The hide is next air-dried and worked with the slicker, at first as usual, but afterwards with a sharp slicker in such a manner that the top of the two strata of grain is "abstracted" by the slicker and the underlying stratum left intact. After the grain is split it is blackened. The black constitutes one of the claims, and is prepared by soaking old iron in young beer or sediment of beer for about four weeks; this solution is applied to the hide after it has received a coat of logwood extract. Train oil, applied softly, serves to fix the black, and the hide is now dried. It is next laid on a blanket and rubbed with a "solution of 100 parts of vaseline oil and 30 parts of ceresin mixed with a quarter of an ounce of nigrosin," boiled together into an embrocation. Ironing, slicking, and glassing of the grain finish the process, except that a gloss is imparted to the grain by applying a size made by boiling a gallon of vinegar with half a pound of glue mixed with a quarter of an ounce of nigrosin, and allowing it to cool and stiffen.

The above is for shoe leather; saddlery leather is similarly treated, save that tallow is applied after the blacking.

—A. G. B.

## XV.—MANURES, Etc.

### PATENT.

*Improvements in or relating to the Treatment of Fish and Fish Offal, and in Apparatus therefor.* J. C. W. Stanley, London. Eng. Pat. 17,205, September 13, 1893.

THE fish or fish offal, with the addition of water, is placed in drums provided with air-tight lids, and these are placed in a tank of water provided with a steam coil. The fish is then boiled until the flesh easily separates from the bone, and the mixture of oil and water is then drained from it. The oil is separated from the aqueous extract by an elaborate system of settling tanks and the aqueous extract precipitated by chemical means.

The solid matter, consisting of flesh and bone, after expressing all the water and oil from it, is mixed with water and transferred to a heating machine, the resulting mixture being passed through sieves. The bones in this way are separated from the fibrous matter, which is afterwards retained by passing over strainers, and can then be dried and used for agricultural purposes or otherwise. The aqueous extract is mixed with that obtained in the first process, and the whole is precipitated by chemical means, the resulting precipitate being removed from the water by a series of settling tanks. This precipitate is collected and dried, and is said to constitute a valuable manure.

—J. G. W.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Cause of the Birotation of Glucose (Dextrose).* B. Tollens. Ber. 1893, 26, 1799—1802.

BÉCHAMP (Bull. Soc. Chim. [3], 9—10, 401, 511) attributes the so-called bi-rotation exhibited by freshly-prepared aqueous solutions of glucose (dextrose) to the formation of a hydrate in solution, which gradually dissociates until at the end of 24 hours the solution contains the anhydrous sugar giving the normal rotation; the author has also arrived at similar conclusions. It has already been shown (this Journal, 1892, 944) that when sugars which exhibit bi-rotation in aqueous solution are examined in very dilute ammonia, the normal rotatory powers are at once observed. When anhydrous glucose is dissolved in aqueous ammonia and in water an absorption of heat (depression in temperature) is soon afterwards observed; in the case of water, however, this is followed by an evolution of heat (rise of temperature), due, apparently, to the union of the water and the sugar. No such subsequent rise of temperature is, however, observed in the case of ammonia. The conclusion therefore that the bi-rotating sugar is glucose hydrate appears to be justified.—A. R. L.

*The Soda-Baryta Process.* Vivien. Zeits. Zuckerind. Böhmen, 1893, 18, 70.

In order to render the juice neutral during diffusion, 1 kilo. of soda is added for 1,000 kilos. of roots. The juice is heated to 85° and 1 kilo. of crystallised baryta is added to 1 m. of it. The precipitate when dry amounts to 8—16 grms. per hl. and contains 20—28 per cent. of barium sulphate, 15—20 per cent. of barium as carbonate and salt of organic acids, and 30—40 per cent. of organic substances; the remaining portion consists of lime, iron, and alumina. This precipitate contains 0.3—0.4 per cent. of the organic substances contained in the juice.

The juice obtained by this process is not raised in purity after the second saturation as is that obtained by the ordinary process, and it has a lower salt quotient than the latter.—A. R. L.

*Estimation of the Quantity and Purity of Masecutes, calculated on the Beetroots, obtained in the Manufacture of Granulated Sugar.* F. Hanns. Zeits. Zuckerind. Böhmen, 1893, 18, 5—8.

THE author's notes refer to a certain Russian factory. He shows that during a single campaign there was obtained from 105,431 kilos. of beetroots, 16,170 kilos., or 15.34 per cent., of masecuite of all grades; that is first, second, third, and fourth products and claires. The mean composition of these masecutes was as follows:—93.4 Brix, 83.5 polarisation, and 89.4 coefficient of purity.—A. R. L.

*Use of Sulphurous Acid in Sugar Manufacture.* K. Abraham, Zapiski 1893, No. 4; through Zeits. Zuckerind. Böhmen, 1893, 18, 67—68.

THE author states that sulphurous acid bleaches certain colouring matters, but by no means all, and the decolorising power is often overrated, as the original colour often returns on exposure to air.

As Drenckmann has shown (Zeits. Zuckerind. Böhmen, 1884—5, 422), carbonic acid exerts a greater purifying effect on the juice during the last saturation than sulphurous acid does.

An alkalinity of 0.05—0.06 is readily reduced to 0.03, by saturation with carbonic acid; if however, it is carried beyond that point the juice darkens. An alkalinity of 0.01 cannot be reduced by sulphurous acid because the normal sulphites have an alkaline reaction, and an excess of sulphurous acid causes inversion.

Employing triple-effect apparatus with juice of an alkalinity of 0.01, sulphurous acid also causes chemical changes, and the evaporating apparatus must be cleaned with soda and hydrochloric acid every week, whereas working with carbonic acid this operation is only needful once during the whole campaign.

The author is of opinion that the disuse of animal charcoal is productive of less masecuite and more molasses, and that the same effect is produced by the use of sulphurous acid.—A. R. L.

*Use of Sulphurous Acid in Diffusion.* Mittleman. Zeits. Zuckerind. Böhmen, 1893, 18, 66 (see also this Journal, 1893, 456).

THE uses of sulphurous acid or of acid calcium sulphite in the proportion of 500 grms. of these substances to 10 q. of roots causes the immediate precipitation of albumin and other organic substances, the lixiviation is effected more readily, and the extracted slices keep better without losing their nutritive value. Sulphurous acid when added to the warm juice protects it from undergoing the lactic fermentation. Aulard found, however, that although sulphurous acid exerted a purifying influence on the juice, it caused it to froth.—A. R. L.

*Estimation of the Amount of Sugar Lost during the Boiling of the Juice.* J. Felemann and F. Herles. Zeits. Zuckerind. Böhmen, 1893, 18, 16—21.

THE loss of sugar due to decomposition during the boiling of the juice may be arrived at by systematically testing the juice and masecuite. For example, a thin juice gave on analysis:—Pol. 10.5 per cent., and sulphated soluble ash 0.31 per cent.; whence  $\frac{10.5}{0.31} = 33.87$ . After boiling to concentrated juice, it gave Pol. 46.3 per cent., sulphated soluble ash 1.38 per cent., or a ratio of  $\frac{46.3}{1.38} = 33.55$ . The masecuite gave Pol. 87.5 per cent., sulphated soluble ash 2.67 per cent., or  $\frac{87.5}{2.67} = 32.77$ . It therefore follows that by evaporating the thin juice to concentrated juice  $33.87 - 33.55 = 0.32$  part of sugar was decomposed, therefore  $(33.87 : 0.32 = 100 : x)$  0.24 per cent. Supposing the thin juice to have been derived from beetroots containing 12.3 per cent. of sugar, the loss of sugar on the roots would

amount to 0.11 per cent. In a similar way, by the conversion of the concentrated juice into massecuite,  $33.55 - 32.77 = 0.78 = 2.3$  per cent., or 0.28 per cent. on the roots. The total loss of sugar by evaporating and boiling, calculated on the roots, is therefore  $0.11 + 0.28 = 0.39$  per cent.

—A. R. L.

*Purification of the Juice in Triple-Effect Apparatus.*  
Mittlemann. Zeits. Zuckerind. Böhmen, 1893, 18, 66—67.

THE author has observed that in proportion as the evaporating apparatus becomes coated with deposits, the alkalinity of the juice sinks and its purity increases. In support of this a table is given showing the results of 15 consecutive days' work, commencing from the day on which the apparatus was cleaned. At the end of the 15th day, although the purity quotient of the juice was 94, as against 90 on the first day, the juice was darker in colour.

Bouvier remarked that the deposits in question consisted mostly of calcium salts; the harmful influence of these on the effect of the evaporating apparatus can be overcome as follows:—In the last member of the evaporating apparatus there are placed iron shavings which have been previously dipped in milk of lime and then treated with carbonic acid. The presence of these incrustated shavings induces the separation of calcium salts up to a certain point, when they are removed and replaced by fresh ones.—A. R. L.

*Defecation of Diffusion Juice with Pulverised Slaked Lime.* Mittlemann. Suer. Belge, 1893, Nos. 14 and 15; through Zeits. Zuckerind. Böhmen, 1893, 18, 64—66.

THE use of slaked lime for defecating the juice has the advantage over the employment of milk of lime, that it dilutes the juice to a less extent, thus:—To 120 litres of juice there was added 16.8 litres of milk of lime containing 16.06 litres of water, whilst by employing 4.07 kilos. of slaked lime containing 15 per cent. of water, the added water amounted only to 0.61 kilo., or 15.45 kilos. less than in the case previously cited. The juice appears to have equal purity as when milk of lime is used. Indeed, during the last campaign results have been obtained which have only seldom been reached. It is said that pulverised lime is injurious to the health of the workmen, but this objection does not apply to slaked lime containing 15 per cent. of water. Before adding the slaked lime the juice is

warmed to  $84^{\circ} - 85^{\circ}$  C. In the course of the discussion Vivien agreed with the author as to the advantages of employing slaked lime for defecating the juice, and as a matter of fact Dervan and Ibled had patented a similar process in 1871. Mauoury said that both caustic and slaked lime had been in use for 10 years in 40 sugar factories in Germany, Austria, and Russia. Bouvier recommended introducing the lime into the juice immediately after it had been slaked in baskets. Dissolution occurs in two minutes, and when a certain amount of fat is also added no scum is formed. No great rise of temperature accompanies the dissolution of the lime. Saturation can be commenced at the expiration of five minutes. The once saturated juice is boiled energetically with addition of lime and then saturated a second time, the following being some of the results obtained:—

Salt Quotients.					
Diffusion juice.....	24.29	24.34	23.15	19.30	22.51
After second saturation	32.85	31.60	31.53	27.38	28.24
Increase.....	8.66	7.26	8.48	7.48	5.73

—A. R. L.

*Continuous "First Saturation," Avoiding the Loss of Carbonic Acid.* T. Franc. Zeits. Zuckerind. Böhmen, 1893, 18, 1—3.

SINCE animal charcoal has fallen into disuse the most vexed question with regard to the purification of the sugar juice is the "first saturation." The saturation gas employed must be as rich as possible in carbonic acid. On this account large lime kilns furnished with ingenious heating arrangements have been erected. Endeavours have especially been made on all sides to prevent as far as possible the great losses of carbonic acid which are occasioned by the use of the existing forms of saturation apparatus. Indeed, experiments with a gas containing 26 per cent. of carbonic acid proved that 9 per cent. of the saturation gas was lost at the commencement of the operation and 19 per cent. at the end. The present invention was devised to obviate this loss, and the author points out that not only is the latter object attained, but the work is expedited.

The "first saturation" is divided into two stages:—(1.) A continuous preliminary saturation with the original gas. (2.) The employment of the gas which escapes from the first operation to finish the process.

Presuming the presence of a mixer, the juice, after mixing with lime, is led into the three high saturators A, B, C, where it rises from the first into the second, and thence into the third vessel, a continuous flow of gas being maintained meanwhile. Both the inflow and the outflow pipes are furnished with valves. From these preliminary saturators the juice enters one of the finishing saturators. The gas evolved from the preliminary saturation passes through the pipe R into the froth retainer F, in the first division of which it takes a downward direction, and in the second an upward direction, thereby destroying the froth, which is returned as juice by the tube S to the preliminary saturator, whilst the gas passes through the tube r to the finishing saturators. The tube R is furnished with valves  $V_1, V_2$ ; the tube r has likewise a valve  $V_3$ . The finishing saturator has also an independent gas and juice delivery tube, so that when desired the saturation can be conducted in the old way. When, for example, the preliminary saturator A is being cleansed the inflow valve is closed from the mixer, the juice run into the finishing saturator, and the operation conducted in the old way. The valves  $V$  and  $V_3$  are closed, whilst A is placed in connection with the empty finishing saturator No. 1, by opening the valves U and  $U_3$ , and the contents of A forced into the vessel No. 1, by means of gas. The same applies to the cleansing of the other two saturators.—A. R. L.

*Filter for Diffusion Juice.* Bouvier. Zeits. Zuckerind. Böhmen, 1893, 18, 64.

THE author makes the following remarks regarding the filtration of the diffusion juice after heating it to  $80^\circ\text{C}$ . and precipitating the albumin:—To assist filtration 1–2 per cent. of fresh saturation sludge (Jopolsky's process), animal charcoal dust or pulverised "Eskarbil" is added. The author has constructed a filter, the upper portion of which is furnished with a removable sheet-iron retainer, having a perforated or wire-gauze sieve which keeps back the pulp and fragments of root slices. When the perforations become clogged the sieve is replaced by another similar one. The under portion of the filter has a double bottom, the upper part of which is perforated. As filtering medium a layer of coarse sand, animal charcoal, wood shavings, or the like, is used. The apparatus is furnished with paddles, which prevent the deposition of the mud. The filtering medium is washed with hot water.—A. R. L.

*Characteristics of Glucose Syrups.* W. E. Stone and C. Dickson. J. Anal. and Appl. Chem. 1893, 7, 317.

See under XXIII., page 178.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Butyl Alcoholic Fermentation, and the Organism which causes it.* M. W. Beyerinck. Rec. Trav. Chim. 12, 141–153.

THE organism supposed by Fitz (Ber. 1882, 15, 867) to be the ferment of normal butyl alcohol was in reality the butyric ferment. Both resemble one another, and belong to a new species of *Granulobacter*, so called because they contain granulose.

The true butylic organism—*Granulobacter butylicum*—was isolated by the author from certain hulled barley—*Hordeum distichon nudum* and *Hordeum vulgare hivalense*. About 20 grms. of the grains are ground, and the flour made into a paste with 100 cc. of boiling water, so that the

temperature of the paste does not rise above  $95^\circ$ , a precaution which it is necessary to observe, as the spores of the butylic organism are killed when heated for a few seconds at  $95$ – $100$ . Other organisms are, however, destroyed below  $95$ . Fermentation is allowed to proceed at  $35$ . After 48 days the starch liquefies, gas is evolved, and the odour of butyl alcohol is apparent. The spores of *Bacillus subtilis* are often present in the fermenting liquid, but these exert no ill-effect on the butylic organism, which is anaerobic and grows in the lower portion of the liquid. When, however, the butyric organism, which is also anaerobic, is present, the fermentation of *G. butylicum* is arrested.

Pure cultures are now made in sterilised fairly acid beer wort in vessels which admit of the exclusion of air; fermentation is conducted at  $35$ , and lasts about 60 hours. The yield of butyl alcohol is about 1–2 per cent. of the flour employed, and the other products are carbonic anhydride and hydrogen; volatile organic acids are quite absent, which distinguishes the organism from the butyric ferment. The organism can be precipitated from the liquid by addition of ordinary alcohol, sufficient of this being added until the mixture contains 70 per cent.; after being dried in the air it forms a brown powder, which is coloured blue by iodine. In this condition the bacteria may be kept for six years without losing their vitality. The organism contains an enzyme—*amylase*—which is secreted upon the outer surface of the bacteria, and which converts starch into maltose and dextrin like the diastase of germinated grain. The granulose mentioned above is deposited in the cell contents of the bacteria.

The spores of the organism retain their vitality in the moist condition for three months only, whilst the bacteria themselves die earlier; the amylase then penetrates the cells and saccharifies the granulose. The bacteria are therefore best preserved in the dry condition.

The author then states that he has recognised two forms of the organism, one which propagates in an atmosphere of oxygen under reduced pressure—the "oxygen form"—and one which is truly anaerobic—the "clostridium form." The former is not easily distinguishable from *Bacillus subtilis*, is very mobile, and is coloured yellowish-brown by iodine; hence it does not contain granulose. When the pressure of oxygen exceeds a certain limit the bacteria become filiform, and finally multiplication is arrested.

The butylic fermentation always commences with a period in which the "oxygen form" predominates, the composition of the evolved gases being  $\text{CO}_2 + 4\text{H}_2$ . When the last trace of oxygen has disappeared, the clostridium form makes its appearance, the development of hydrogen diminishes, and that of carbonic anhydride increases until, at the close of the fermentation, the composition of the evolved gases is  $5\text{CO}_2 + \text{H}_2$ . The principal phase of the fermentation is characterised by the abundance of the "clostridium form." The spindles have at one extremity an ellipsoidal cavity which encloses a spore of the same shape; these spores may be heated at  $100^\circ$  for some seconds without being killed. The anaerobic cultures of the ferment are best obtained at a temperature of  $10$ – $15^\circ$  with solutions of glucose or starch in water, to which 0.05 per cent. of potassium hydrogen phosphate has been added.—A. R. L.

*The Glucosides of the Alcohols.* E. Fischer. Ber. 1893 26, 2400–2412.

THE only method known at present for the artificial preparation of glucosides is that devised by Michael (Comptes rend. 89, 355), which depends on the interaction of aceto-chlorhydrase with the alkali derivatives of phenols. It is, however, restricted to the latter compounds; and, on account of its complexity and the poorness of the yield of product, it has only been employed with success in a few cases. The author finds that when hydrogen chloride is passed into a solution of glucose in methyl alcohol the methyl derivative  $\text{C}_6\text{H}_{11}\text{O}_6 \cdot \text{CH}_3$ , which he proposes to call methyl glucoside, is formed. It is best prepared by mixing a very concentrated aqueous syrup of glucose with a saturated solution of hydrogen chloride in methyl alcohol. It is a crystalline compound having a

sweet taste; it melts at  $165^{\circ}$ — $166^{\circ}$ , and is readily soluble in water. The solution is dextro-rotatory—

$$[\alpha]_{D_{20}} = +157.5.$$

but it does not reduce Fehling's solution.

The reaction above indicated seems to be available for all alcohols; in the case of glucose it has been proved with ethyl, propyl, amyl, isopropyl, allyl, and benzyl alcohols, as also with ethylene glycol and glycerol. In certain cases it is rendered difficult on account of the small solubility of the sugar in the alcohol. It may even be employed for the hydroxy acids, as was proved by the preparation of lactic glucoside. When the sugar is completely insoluble in the alcohol, which is the case with many compounds of the aromatic and terpene series, the method cannot be employed, but in such cases, in the place of glucose, acetochlorhydrate, or pentaacetylglucose, both of which are readily soluble in ether, benzene, and chloroform, may be used. The acetyl groups are here split off by the hydrochloric acid, and the products are those already mentioned. The author speculates upon the probable constitution of these compounds and of the sugars from which they are derived, but no definite conclusions are arrived at. It is interesting to observe that he regards their structure as analogous to that of the bioses—maltose, milk sugar, &c. The latter are made up of two hexose residues, whilst the new compounds are made up of a hexose residue and a simple alkyl group.

The bioses are hydrolysed by hydrochloric acid, and cannot therefore be converted into glucoside-like compounds by the method above indicated.

The new synthetic compounds resemble the natural glucosides in their properties. They are unattacked by boiling alkalis, Fehling's solution, and phenylhydrazine; if, however, they be heated with dilute acid they are readily hydrolysed into their components: they are likewise hydrolysed by the invertase of yeast. *Benzylglucoside* and *ethylrhannoside* have a bitter taste; and it would seem possible that many naturally occurring bitter principles may belong to this class of compounds.

Gautier's so-called diglucose (Bull. Soc. Chem. 1874 [2] 22, 145), which he obtained by saturating an alcoholic solution of glucose with hydrogen chloride, is in reality ethyl glucoside; this being so, the only hexabiose which has up to the present been obtained synthetically, is the author's isomaltose.—A. R. L.

#### PATENTS.

*Improvements in Preserving Yeast for Transport.* J. Heron, Battersea. Eng. Pat. 3077, February 11, 1893.

THE yeast is pressed and mixed with a solution of glucose containing only about 10 to 12 per cent. of water, or it is submitted to more than the ordinary pressure so as to make it drier than is customary, and mixed with a solution of glucose of the concentration usually employed for brewing purposes. The two are thoroughly incorporated, and the mixture put into moulds and left to set. A mixture of one part by weight of ordinary pressed yeast and four parts by weight of extra concentrated glucose is recommended.—J. G. W.

*Treating Brewers' Spent Hops, Wet and Dry, for the Production of Fodder and Litter.* J. J. Adkins, London. Eng. Pat. 17,268, September 14, 1893.

FOR use as a substitute for ensilage the wet and fresh hops are flavoured with essences of caraway, coriander, and aniseed, with the addition of fennigreek and salt. As a substitute for hay the hops are dried and flavoured with the same mixture. For use as litter the hops are simply dried.

—J. G. W.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

### (A).—CHEMISTRY OF FOODS.

*The Sterilisation of Bread and Biscuit after Withdrawal from the Oven.* Balland and Masson. Comptes rend. 1893, 117, 797.

See under XVIII. B., page 169.

*The Determination of Casein in Cows' Milk.* L. L. Van Slyke. J. Amer. Chem. Soc. 15, 635.

See under XXIII., page 181.

#### PATENTS.

*A Method of and Apparatus for Preserving Meat, Cereals, and other Animal or Organic Substances; Destroying Parasites and Vermin, Extinguishing Fires, and Disinfecting Leather, Fabrics, and the like.* J. Vigerie, Lille, France. Eng. Pat. 2694, February 7, 1893.

THESE several purposes are effected by the use of carbon dioxide under pressure, obtained from a cylinder of the liquid gas, the apparatus for preserving substances consisting simply of a receptacle for those substances, into which carbon dioxide can be forced. The apparatus for extinguishing fires is merely an arrangement for forcing carbon dioxide gas into water, and, when required, forcing out the water thus impregnated with the gas by means of the expansion taking place during the change from the liquid to the gaseous state.—J. G. W.

*An Improved Cattle Food.* G. Holland, Glasgow, Lanark, N.B. From G. Holland, Ahlfelde, Prussia. Eng. Pat. 3526, February 17, 1893.

THIS invention relates to a cattle food prepared by mixing molasses or treacle (100 parts) with maize, rice, wheat, rye, or bran, dried beer dregs, or any other feeding meal (100 parts) in a kneading machine; the dough is pressed into flat cakes and baked in an oven or drying apparatus, after which the cakes are ground and mixed in a dry condition with the ordinary food. The molasses food may also be made in a dry, loose state, the proportion of the bran or feeding meal being then 100 to 70; the mass is also worked up with the kneading machine. After standing for some time the dough is laid upon plates and baked.

—A. R. L.

*Improvements in Fluid Meats and the Process of Manufacturing Same.* W. Clark, Montreal. Eng. Pat. 4486, March 1, 1893.

LEAN beef is cut up into small pieces and cooked in a digester kettle. When finished, the liquor is separated from the beef by straining. The beef is minced and reduced to a homogeneous mass by passing through a series of perforated plates, and then mixed with the liquor, formerly separated, after the latter has been skimmed to remove all fat. To this mixture is added 10—15 per cent. of "essence of wheat" (Eng. Pat. 4487, 1893; see succeeding abstract), and the whole thoroughly amalgamated. This mixture is again mixed with an equal quantity of a gelatinous extract of beef, obtained by boiling the sinew and muscle in a digester kettle under pressure. It is claimed that the advantages of this combination of ingredients are that the nutritious constituents, which are necessarily insoluble, remain in suspension for a considerable time, while at the same time a rich natural beef flavour is secured and ready digestibility attained.—J. G. W.

*Improvements in Food Preparations and in their Manufacture.* W. Clark, Montreal. Eng. Pat. 4187, March 1, 1893.

WHEAT germs are soaked in water for two hours, and the solution, which contains the soluble albuminoids, drawn off. This is mixed with extract of meat (Eng. Pat. 4486, 1893; see preceding abstract); or it is coagulated under pressure and the resulting clot subjected to pressure in a press, and in this dry state incorporated with solid meat-extract.

—J. G. W.

*Improvements in the Treatment and Packing of Meats or like Articles of Food for Rendering them fit for Use for Army Rations or Analogous Uses.* P. Pfeleiderer, London. From C. J. H. Warden, Bengal, and W. A. Billings, Meerut. Eng. Pat. 6663, March 29, 1893.

MEAT, from which all fat, skin, and bone have been removed, is minced and pressed to express as much as possible of the juices. The cakes thus produced are dried in a current of warm, dry air, at a temperature rising from 120°—212° F. The expressed juices are concentrated in a vacuum-pan to the consistency of treacle, incorporated with the coagulated albumen, and then intimately mixed with the dried meat-fibre and formed into cakes, which are desiccated at a temperature of 160°—170° F. These cakes are coated with a layer of fat by plunging into a bath of melted meat-fat or butter, and are packed by enclosing each cake in paper impregnated with fat, and the whole in lead or tin foil, which can be soldered at the seams. The whole is enclosed in strong parchment paper, cemented at the joints by a solution of gelatin and potassium bichromate, which is afterwards exposed to the light to render it insoluble.—J. G. W.

#### (B.)—SANITARY CHEMISTRY AND WATER PURIFICATION.

*The Sterilisation of Bread and Biscuit after Withdrawal from the Oven.* Ballard and Masson. Comptes rend. 1893, 117, 797—799.

THE paste used in the manufacture of the regulation military bread has a mean acidity equal to 0.15—0.2 per cent., or on the dry substance 0.29—0.38 per cent. Calculated as sulphuric acid, the acidity of the crumb after baking will be approximately the same. The authors find that the combined effects of this acidity and the temperature of baking are generally sufficient to render the bread sterile; only certain spores which are resistant to elevated temperatures, survive, and ultimately, under favourable conditions, develop. In the case of bread manufactured with yeast the acidity is less, and consequently the sterilisation is not assured to the same degree. In all cases, however, pathogenic germs, notably the bacillus of typhoid and cholera, which offer less resistance to heat, ought to be destroyed.—A. R. L.

#### PATENTS.

*Improvements in Filters for the Removal of Bacteria and Germs from Water and Sewage.* F. P. Candy, Batham, Surrey. Eng. Pat. 1448, December 9, 1893.

THE object of the process is to provide a permanent filter bed for the retention of bacteria and germs, independent of deposition from the impure water, the accumulation of which is necessarily uncertain. Oxides, or better hydroxides, of iron, manganese, or aluminium, carbonised or calcined iron carbonate, or other suitable materials, are finely powdered and passed through a sieve having about 60 meshes to the lineal inch, and mixed with about the same bulk of wet sand. A layer of half an inch or more of the mixture is placed on the body of the filter bed.

It is preferable to remove any suspended matter from the water or sewage before running on to the above filter. Besides bacteriological purity, increased chemical purity is nearly always obtained.—N. H. J. M.

*Improvements in the Method of and Apparatus for Purifying Water.* A. T. Walker, Reading, Berks. Eng. Pat. 2807, December 9, 1893.

THE water first passes through a series of upright sieves, which may be readily removed and replaced. It then passes through pipes into a tank, from which it overflows into a second tank containing clean furnace or other coke, resting on perforated bricks, under which the water passes into a third tank, from which it overflows into a fourth chamber containing granulated "polarite." After the water has passed downwards through the "polarite," it enters a fifth chamber, whence it overflows into the sixth compartment, which is also filled with "polarite." The water is finally collected in reservoirs for distribution. The polarite beds are not less than 2.5 ft. deep, but of comparatively small superficial area.—N. H. J. M.

*Improvements in Apparatus for Filtering and Purifying Water.* W. Webster, Blackheath, Kent. Eng. Pat. 1676, December 9, 1893.

THE apparatus consists of a vessel containing black oxide of iron, connected from below by means of a long, narrow tube with a small chamber having a perforated bottom and charged with spongy platinum. The long connecting tube has a lateral branch terminating in a short tube parallel to the long tube. The upper end of the short tube is drawn out so as to leave a small opening, whilst the lower end is connected with an inverted bell-jar, which dips into a small water tank provided with a suitable electrolysis apparatus.

The water first filters through the iron oxide, passes down the long tube, where, at the point of junction with the lateral tube, it carries down bubbles of air, and oxygen, or oxygen alone, as may be required. On coming into contact with the spongy platinum it is sufficiently charged with oxygen to effect the oxidation of any organic matter which may be present.—N. H. J. M.

*An Improved Apparatus for Obtaining Distilled and Sterilised Water.* J. Nagel, Chemnitz, Germany. Eng. Pat. 20,296, December 9, 1893.

THE apparatus consists of a boiler with heating tubes on Field's system, an upcast tube through which the steam passes into an upper chamber. This chamber is provided with a sieve, through which the partly-condensed steam passes downwards through a set of tubes surrounding the upcast tube and enclosed in a cylinder kept cold by running water. At the lower end of the tubes there is a reservoir for collecting the distilled water. The water used for cooling may be used for distillation.

When water is to be merely boiled, the upcast tube is closed with a valve. The pressure of the steam forces the water through a smaller tube into the upper chamber, from which it flows downwards through the sieve and the cooling pipes into the collector.—N. H. J. M.

*Process for Treating the Effluent from Electrolytically or Chemically Purified Sewage for Neutralising its Alkalinity and for the Production of By-Products therefrom.* W. Webster, Blackheath, Kent. Eng. Pat. 1675, December 9, 1893.

THE effluent from the purified sewage is treated with Portland cement, fluxed lower-grey chalk ("soap"), or caustic lime previously suspended in water. The amount of substance required varies from 8 grains to 100 grains per gallon. In subsiding, the solid matter carries down the suspended matter. The effluent is then brought into intimate contact with the gaseous products from the burning of Portland cement, namely, sulphurous and carbonic anhydrides and carbonic oxide. This is effected by

running the water over a series of shallow trays in a closed vessel, through which the gases are made to pass in a contrary direction; or else by letting the water fall from the top of a tower, through which the gases pass upwards. In this manner the alkalinity of the water is neutralised, and any lime remaining in suspension precipitated. The precipitates are converted into cement by burning.

—N. H. J. M.

### (C).—DISINFECTANTS.

*Stability and Preservation of Dilute Solutions of Corrosive Sublimates.* L. Vignon. *Comptes rend.* 1893, **117**, 793.

See under XX., page 171.

### PATENT.

*Improvements in Disinfecting.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 18,370, December 16, 1893.

The authors have already described apparatus for electrolysing bleaching liquors containing chlorides, the manufacture of a liquor for disinfecting and bleaching purposes by electrolysis, the disinfecting of impure liquids by electrolysis in presence of chlorides, and apparatus for electrolysing sewage (compare this Journal, 1887, 126, 321, and 764).

By the method now described, an electrolysing plant, as already described (*loc. cit.*), is provided with reservoirs, where water to which chlorides have been added, or sea water without further addition, is electrolysed. The water is then conducted, as a disinfectant, to drains, closets, and other places as required. The liquid need only contain about 0.1 per cent. of chlorine, and its use is therefore not attended with any unpleasant odour.—N. H. J. M.

## XIX.—PAPER, PASTEBOARD, Etc.

*Brown Paper from Wood.* Papier Zeit. **18**, 2653.

A WOOD-PULP boiler made by G. Schumann, of Zeitz, is described and illustrated. It is constructed of wrought iron and lined with sheet copper to protect the shell from the action of the organic acids from the wood.

The most usual size is 4.5 metres long, by 1.5 metre diameter, and 8 cb.m. capacity. Steam of 6 atmospheres pressure is used, and is left on for from 8 to 18 hours. The longer the steaming, the darker the colour of the material produced. Water of condensation is removed at the bottom, and with it the oil of turpentine from the wood. The turpentine is sometimes recovered and used. In order to cool down the boiler and wash the wood, the former is filled with water and emptied two or three times before the contents are removed. The lining is 2.5 and 6 mm. thick, and is attached to the iron shell by copper-plated, or solid copper rivets; at the manholes the lining is flanged over. In order to test the tightness of the copper lining, holes are pierced through the iron shell, and water pumped in, when, if the lining be not tight, water will leak into the interior, and thus indicate the leaks.—R. B. P.

### PATENTS.

*Coating or Covering Paper with Aluminium.* W. Ibbotson, London. Eng. Pat. 23,603, December 22, 1892.

THE surface of the paper is coated with adhesive matter, and the latter covered with laminated or powdered aluminium, or powdered aluminium is mixed with adhesive matter and spread on the surface of the paper by brushes or any other manner convenient. The claim is "Paper coated with aluminium."—E. G. P. T.

*Improved Process for Treating the Black Ash Residuum of Wood Pulp Manufacture.* L. S. Langville, New York, U.S.A. Eng. Pat. 18,519, October 3, 1893.

THIS invention relates to a process described in Eng. Pat. 13,847, 1892 (this Journal, 1892, 935), for the production of a carbon product obtained from the black ash resulting as a residuum of wood pulp manufacture.

By the new process, the black ash residuum is mixed with water and caused to flow through a trough with riffles in its bottom at right angles to the trough; the carbon, being lighter than the foreign substances mixed with it, floats, while the impurities sink and are caught in the riffles. The liquor running from the tank is treated with weak hydrochloric acid, and the carbon washed by the aid of steam heat, dried, and powdered. It is then well adapted for making electric light carbons and India ink, and as an ingredient of writing ink, gunpowder, paint, &c.

—E. G. P. T.

*Improved Sensitised Paper for Photographic Purposes.* A. Hiesekiel, Berlin. Eng. Pat. 20,042, October 24, 1893.

THE improved paper is prepared in the usual way, but of sufficient substance to receive the impress, from rollers or otherwise, of a granular surface; the object being so to break up the surface of the paper as to give the printed matter or photograph the appearance of line or other engraving or etching effect.—E. G. P. T.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Formation of Ozone at High Temperatures.* O. Brunck. Ber. 1893, **26**, 1790—1794.

IT is a well-known fact that oxygen prepared by heating a mixture of potassium chloride and manganese dioxide has an intense odour resembling that of chlorine, and statements as to the amount of chlorine in oxygen so prepared are very numerous. If the intense odour were really due to the production of chlorine in the reaction, the residual mixture of salts should give on extraction with water an alkaline solution containing potassium manganate, whereas experiments have convinced the author that the aqueous extract is invariably neutral and colourless. This circumstance, together with the properties of the gas of rendering potassium iodide-starch paper blue, suggested that the gas might contain ozone, which supposition was confirmed. (Compare McLeod, *Proc. Chem. Soc.* 1894, and March number of this Journal, under XX.)

A series of experiments led to the result that ozonised oxygen can be heated for a short time not only to the decomposition point of potassium chlorate, but also at a red heat, without destroying the ozone. The gas evolved from potassium chlorate and manganese dioxide after washing it with alkali, not only liberates iodine from potassium iodide, but also oxidises alcohol to aldehyde; it loses its odour and oxidising properties when passed over a short layer of manganese dioxide at the ordinary temperature. The active oxygen thus produced appears to differ somewhat from ordinary ozone, thus:—Its odour is exactly that of chlorine; it withstands a higher temperature, and does not attack mercury nor organic substances, such as caoutchouc, so readily as ordinary ozone. Pure potassium chlorate yields no ozone, but the presence of the least trace of indifferent substances, such as silica, causes its formation. A mixture of equal parts of potassium chloride and manganese dioxide yielded a gas containing 0.3 per cent. of active oxygen; whilst when the relative amount of manganese dioxide used was 25 times that of the chlorate, the gas contained 1.55 per cent. of active oxygen. A preliminary account is given of experiments, now in progress, on the behaviour of manganese dioxide and other oxides at high temperatures.—A. R. L.

*Basic Bismuth Gallate (Dermatol).* H. Causse. *Comptes rend.* 1893, **117**, 232—234.

Basic bismuth gallate, better known as dermatol, was obtained by R. Fischer (*Pharm. Zeit.* 1891). The author has prepared it in small yellow crystals of the composition  $C_7H_5O_3Bi + 2H_2O$  by adding gallic acid to a solution containing bismuth and potassium nitrates in acetic acid. It is insoluble in water, but dissolves in mineral acids, and is very sensitive to the action of light and air. *Bismuth pyrogallol*,  $C_6H_3O_3Bi$ , is obtained in a similar manner when pyrogallol is substituted for gallic acid.—A. R. L.

*Stability and Preservation of Dilute Solutions of Corrosive Sublimate.* L. Vignon. *Comptes rend.* 1893, **117**, 793—795.

When a solution containing 1 grm. of mercuric chloride per litre is kept in an open vessel at a temperature of  $15^{\circ}$ — $20^{\circ}$ , a white precipitate forms and the titre of the solution rapidly diminishes, and consequently also the antiseptic value; the same phenomenon is observed if the solution be kept in a closed vessel, but the change is less rapid. The presence of colouring matters appears to retard the alteration of the solution, and in this respect indigo carmine is superior to fuchsin.—A. R. L.

*Some Decompositions of Quinine.* Zd. H. Skraup. *Monatsh. Chem.* **14**, 428—434.

The action of reagents on the trihydriodide of quinine,  $C_{20}H_{24}N_2O_2 \cdot 3HI$ , resulting in the elimination of iodine, gave rise to a number of mixtures of bases, some of which mixtures were considered to be new compounds (*cf.* *Monatsh. Chem.* **12**, 688; this *Journal* 1892, 263). Their separation was a matter of some difficulty, and hence certain of the statements in the preceding paper require modification. Two compounds *pseudoquinine*,  $C_{20}H_{24}N_2O_2$ , and *nichine*,  $C_{19}H_{23}N_2O_2$ , have, however, been isolated, and these bases, together with regenerated quinine, are always formed in varying quantities when the above trihydriodide is treated with various reagents. *Nichine* can be isolated by boiling the nitrate of the base,  $C_{20}H_{23}IN_2O_2$ , for some time with dilute alcohol. The formation of *nichine*,  $C_{19}H_{23}N_2O_2$ , from quinine,  $C_{20}H_{24}N_2O_2$ , appears to be accompanied by an evolution of formaldehyde. *Pseudoquinine* trihydriodide, like quinine trihydriodide, yields with alcoholic potash a mixture of *nichine*, *pseudoquinine*, and quinine, so that the two latter bases can be mutually converted into one another. *Nichine* trihydriodide, on the other hand, when similarly treated, yields principally *nichine*, together with a small quantity of a new base, *isonichine*,  $C_{19}H_{23}N_2O_2$ .

For decomposing the trihydriodide of quinine with alcoholic potash, one part of the substance is heated for rather more than an hour with 14 parts of a mixture of equal weights of alcohol and water containing 1.5 parts of caustic potash. The solution is then evaporated to half its bulk, and the bases which separate are dissolved in 7 parts of alcohol and 0.75 part of oxalic acid are added, when acid *nichine* oxalate separates; on further evaporation, acid *pseudoquinine* oxalate separates out, and the mother-liquor contains quinine. *Nichine*,  $C_{19}H_{23}N_2O_2$ , crystallises in needles with  $2H_2O$  and melts at  $102^{\circ}C$ . It becomes anhydrous at  $100^{\circ}C$ , and then melts at  $146^{\circ}C$ . In a dilute solution in presence of sulphuric, nitric, or oxalic acids, but not of hydrochloric acid, it shows a blue fluorescence, and it also gives the quinine reaction with chlorine water and ammonia. Its solution in alcohol is levo-rotatory—

$$[\alpha]_D^{20} = -129.021^{\circ}.$$

On warming the base with 5 parts of hydriodic acid of sp. gr. 1.7, it is converted into the compound—

which is insoluble in alkalis. If this compound be decomposed with dilute alcoholic potash, two-thirds of the *nichine* can be precipitated with oxalic acid, whilst a new base, *isonichine*,  $C_{19}H_{23}N_2O_2$ , which melts at  $209^{\circ}C$ , and crystal-

lises in scales, can be isolated from the mother-liquor. By heating *nichine* with 10 parts of hydriodic acid of sp. gr. 1.7 it loses one methyl group giving—

*Pseudoquinine*,  $C_{20}H_{24}N_2O_2$ , melts at  $191^{\circ}C$  and fluoresces like quinine in solutions containing nitric, sulphuric, or oxalic acids, but not with hydrochloric acid, and it also gives the reaction of quinine with chlorine water and ammonia. One hundred parts of alcohol at  $22^{\circ}C$  dissolve 0.363—0.388 part, and  $[\alpha]_D^{20} = -161.41^{\circ}$ .

The trihydriodide is possibly identical with that of quinine. (See also this *Journal*, 1893, 707.)—T. A. L.

*The Behaviour of the Calcium Salt of Veratric Acid on Dry Distillation.* W. Heinisch. *Monatsh. Chem.* **14**, 455—461.

On briefly summarising the results of the investigation, it would appear that the calcium salt of veratric acid, when subjected to dry distillation under the conditions observed, gave the methyl ether of veratric acid and veratrol as chief products, together with a little guaiacol and veratric acid. The ether formed the largest proportion. Only small quantities of pyrocatechol could be detected in the residue. In connection herewith it may not be inopportune to call attention to the fact that phenol is found in the distillate when the calcium salt of anisic acid is distilled.—T. A. L.

*Rhodinol: the Chemical Principle contained in the Liquid Portion of Otto of Roses.* P. Barbier. *Comptes rend.* 1893, **117**, 177—178.

Eckart has shown (this *Journal*, 1892, 265) that rhodinol,  $C_{10}H_{16}O$ , is a primary alcohol containing two ethylenic bonds and giving valeric acid on oxidation. It is isomeric with linalcol and geraniol. Rhodinol is an oily liquid boiling at  $126.5^{\circ}$  under a pressure of 16 mm., and having a specific gravity at  $0^{\circ} = 0.8956$ ; its refractive index for  $\lambda$  645 is  $n = 1.4653$ , and for  $\lambda = 452.6$   $n = 1.4795$ , and its specific rotatory power is  $[\alpha]_D^{20} = -2.37^{\circ}$ . Hydrogen chloride acts on rhodinol as a dehydrating agent, producing dipentene dihydrochloride. If rhodinol be heated in a sealed tube at  $180^{\circ}$  with acetic anhydride, the acetyl derivative  $C_{10}H_{17}(OC_2H_5O)$  is formed; it is a colourless, mobile oil boiling at  $131^{\circ}$  under a pressure of 15 mm., and having a specific gravity at  $0^{\circ} = 0.9214$ ; its refractive indices are  $n = 1.4526$  for  $\lambda = 645$ , and  $n = 1.4661$  for  $\lambda = 452.6$ . When the acetyl derivative is treated with alcoholic potash, rhodinol is regenerated, so that of the two theoretically, possible stereochemical formulae, rhodinol must possess the stable form.—A. R. L.

*Mercury Gallate: A New Antisyphilitic.* Brousse and Gay. *Comptes rend.* 1893, **117**, 284—285.

The successful results obtained by numerous experimenters in the treatment of syphilis by mercury tannate, suggested the use of mercury gallate for the same purpose. The compound was prepared by titrating gallic acid (37.6 grms.) and yellow mercuric oxide (21.6 grms.) with water (25 cc.), allowing the paste remain for two days, reducing the dried mass to powder, and finally drying it over concentrated sulphuric acid. It is of a dull greenish-black colour, and contains 37 per cent. of mercury. The compound is administered in the form of pills, which are made by kneading mercury gallate (0.05 grm.) and extract of cinchona (0.1 grm.); the dose is 2–4 pills *per diem*. The absorption is rapid, and mercury may be detected in the urine 24 hours after the first dose. As a net result, mercury gallate is found to be a powerful antisyphilitic comparable with mercuric chloride or iodide, and having the advantage over these compounds in that the amount of mercury which the therapeutic dose contains, is not dangerous.—A. R. L.

*Manufacture of Morphine Sulphate.* J. Calvert. J. Anal. and Appl. Chem. 1893, 7, 331—333.

THE liquid resulting from the extraction of opium with water is precipitated with an alkali, and the crude base taken up with dilute sulphuric acid, the solution filtered through animal charcoal, and concentrated to 4.5 to 0.5° B., after which it is run into the crystallising apparatus. The latter is a leaden tank, about six inches in depth, the other dimensions being commensurate with the volume of the solution; it is hinged on a frame, and has an outlet with a plug at the lower end for drainage. "The solution is stirred gently every few minutes until crystals commence to form on the surface, and then, carefully stirring, when the solution has come to the right temperature, the morphine sulphate crystallises suddenly into a solid mass." At the end of 48 hours the plug at the lower end of the tank is removed and the mother-liquor is allowed to run off, at first slowly, and afterwards, by elevating the apparatus, the last of the mother-liquor is removed. The drainage requires several days. The crystals in the apparatus are then cut up into pieces of the shape of bricks (commencing at the upper end), which are placed on an absorbent and removed to a drying room. When the bricks are dry, the colouring matter, which always comes to the surface, is removed by slicing off the dark portions. The bricks are then cut into slices, and the latter crumbled in the hands.—A. R. L.

*The Melting Point of Cocaine Hydrochloride.* O. Hesse. Liebig's Annalen, 1893, 276, 342—344.

IN view of the medicinal importance of cocaine hydrochloride, and the methods of testing its purity, the author quotes Kinzel's observation (Pharm. Zeit. 38, 25) that pure cocaine hydrochloride melts at 200°—202°, and that a lower melting point is indicative of impurities; this value has been confirmed by other observers.

Antrick, Einhorn, and Marquardt obtained, however, the value 181.5°, whilst the author, who conducted the experiment in a Roth's apparatus, found the value 186°. A repetition of the experiment has established the accuracy of the last value when the determination is carried out in the manner specified: whereas if the melting point be determined in a sulphuric acid bath a value near to 200° is obtained. The author has also observed that when the hydrochloride is raised in temperature very slowly in a sulphuric acid bath, a thermometer being used the mercury reservoir of which is not too small, the value 186° is obtained for the melting point; when, however, the temperature is rapidly raised, and a thermometer having a very small mercury reservoir used, the apparent temperature of fusion is 200°—202°.—A. R. L.

*The Combination of Hydrocarbons with Picric Acid and other Nitro-Compounds.* W. A. Tilden and M. O. Forster. Proc. Chem. Soc. 1893 [129], 239—240.

THE authors have instituted a compound described by Lextrait in 1886, which is formed by heating picric acid with pinene. It contains the elements of picric acid and a terpene, but differs from the picates of other hydrocarbons in forming a peculiar potassium salt, in yielding picramide

and borneol when submitted to the action of alcoholic ammonia, and in forming borneol and not simply a hydrocarbon under the influence of aqueous alkalis.

The authors have also instituted experiments on the behaviour of other hydrocarbons with nitro compounds generally, from which it appears that, in order that a compound may be formed, at least two nitro groups must be present in the nitro derivative concerned. They conclude that the oxygen of the nitro groups affords the link which, in ordinary cases, binds the hydrocarbon to the nitro compound, while in the case of the pinene derivative the oxygen of the hydroxyl is probably also involved.

*Contributions to our Knowledge of the Aconite Alkaloids. VII. On Picroaconitine.* W. R. Dunstan and E. F. Harrison. Proc. Chem. Soc. 1894 [132], 6.

"Picroaconitine" can no longer be retained as the name for an alkaloid derived from *A. Napellus*. The present investigation has shown that this plant contains, besides aconitine and the non-toxic isaconitine and aconine, a very small quantity of an amorphous alkaloid yielding crystalline salts, which has been named homisaconitine, and generally a considerable quantity of a base which neither crystallises nor furnishes crystalline salts.

*Contributions to our Knowledge of the Aconite Alkaloids. IX. The Action of Heat on Aconitine.* W. R. Dunstan and F. H. Carr. Proc. Chem. Soc. 1894 [132], 7.

THE authors find that when aconitine is heated at its melting point (188°—190°) it loses about 10 per cent. of acetic acid, which distils over, leaving a new alkaloid which they propose to name pyraconitine—

Pyraconitine is obtained in the form of an amorphous varnish, sparingly soluble in water, but readily in alcohol, chloroform, and ether. It has no effect on polarised light, and is not poisonous in small doses. The alkaloid readily dissolves in acids, forming salt which can be crystallised.

The solutions of the chloride, bromide, and iodide salts have a bitter taste, but are not toxic, at all events in small doses.

Pyraconitine and its salts readily undergo hydrolysis when heated with dilute acid or with water in a closed tube. Potash and soda quickly hydrolyse the alkaloid, even in the cold, but ammonia does so only very slowly. The sole products of hydrolysis are benzoic acid and an alkaloid which has been named pyraconine—

Pyraconine is an amorphous base resembling aconine in its properties, but differing from it in several respects. It is soluble both in water and ether. The aqueous solution has a somewhat sweet taste, and is levo-rotatory—

$$[\alpha]_D = -90.99^\circ.$$

It combines with acids to form crystalline salts which are very soluble in water.

The salts of aconitine also furnish pyraconitine, losing acetic acid when heated at about 190°. Isaconitine and aconine, however, do not undergo a similar decomposition. The authors consider it probable that the production of acetic acid from aconitine may serve as the basis of a process for the estimation of this alkaloid.

*Contributions to our Knowledge of the Aconite Alkaloids. X. Further Observations on the Conversion of Aconitine into Isaconitine.* W. R. Dunstan and F. H. Carr. Proc. Chem. Soc. 1894 [132], 8.

IN a former communication, the authors showed that when certain aconitine salts are heated at 100° in slightly acid solution they are very slowly changed into the salts of isaconitine. They have since found that this conversion

may be effected with great rapidity by heating a neutral aqueous solution in a closed tube at  $120^{\circ}$ – $130^{\circ}$  during from two to three hours, when the aconitine salt disappears, often so completely that the solution produces a tingling sensation on the tongue. The isaconitine is separated from the solution, which has been rendered alkaline with ammonia by repeated extraction with ether.

It has also been proved that the production of isaconitine invariably precedes the hydrolysis of aconitine into aconine and benzoic acid, not only when the hydrolysis is effected by acid, but also when water alone is used as the hydrolytic agent. In previous experiments, the formation of isaconitine during the hydrolysis of aconitine in presence of alkali could not be proved, owing to the rapidity with which aconine is produced. If, however, a considerable excess of an aqueous solution of soda be added to a solution of an aconitine salt, and the precipitated alkaloid be allowed to stand in contact with the cold alkaline solution until some of the alkaloid is dissolved, extraction with ether separates a notable quantity of isaconitine, as well as the unchanged aconitine. It therefore appears that the non-toxic aconine is really the product of the hydrolysis of the non-toxic isaconitine into which the aconitine first changes.

The observations recorded in the foregoing abstract, which prove that aconitine salts as well as the alkaloid lose acetic acid when they are heated, led the authors to look for the production of this acid when solutions of these salts are heated. It has been found that some acetic acid is formed when aconitine salts are heated with water in the manner above described, and also when these salts or the alkaloid are hydrolysed.

#### PATENT.

*A Manufacture of Pharmaceutical Preparations for Use more particularly in Cases of Anæmia and for Weak Throats.* W. Webster and T. Moore, Blackheath, Kent. Eng. Pat. 2884, February 9, 1893.

See under XI., page 161.

### XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

#### PATENTS.

*Improved Sensitised Paper for Photographic Purposes.* A. Heseckel, Berlin. Eng. Pat. 20,042, October 24, 1893.

See under XIX., page 170.

*A New or Improved Method of Treating Canvas, Shirting, Silk, Paper, and like Substances, for the Purpose of Rendering the same Sensitive to Light.* G. J. Junk, Berlin. Eng. Pat. 21,249, November 8, 1893.

A mixture of bromide and iodide of silver is precipitated at a temperature of  $28^{\circ}$  C. in the presence of a trace of gelatin, and is maintained at that temperature for an hour or so with constant agitation, so as to prevent the precipitate from coagulating. It may then be washed in a centrifugal machine to remove the alkaline nitrate, and is finally well mixed with a cold solution of arrowroot which has been boiled in water till perfectly clear. The fabric or paper to be sensitised is then coated by means of a sponge in the dark room and dried, and if the emulsion has not been washed it is soaked in water for an hour and dried again. Development takes place as for an ordinary gelatino-bromide emulsion. Prints so made lend themselves far more readily to finishing in crayons, oils, or water-colours than when the fabric has been coated with an emulsion in gelatin, as there is no fear of the whole film stripping off the canvas. Paper prints made with the arrowroot emulsion may also be finished both with chalk and the brush, which was impossible before "owing to the impenetrable nature of the gelatin film." Starch may be used instead of arrowroot, but the results are said to be less favourable.—F. H. L.

### XXII.—EXPLOSIVES, MATCHES, Etc.

*On Explosives.* F. Biltz. Ber. 26, 1378–1383.

St. Frederick Abel, in his investigations (Comptes rend. 69, 105; 78, 1227, 1301, 1362, 1432), showed that a large number of explosives cannot be exploded by merely heating, but that it will only cause them to burn quietly, or partially explode, and that to produce a sharp explosion a detonator is required, i.e., another explosive. All explosives are not suited for this purpose, even if more powerful than actually required. To explain this relation between detonator and explosive, Abel assumes that there must be a certain synchronism of the explosive waves of the two in order to effect the explosion, and proved experimentally that the mechanical blow of the detonator was not of itself sufficient to cause the explosion of the other material. V. Meyer (Ann. d. Chem. 264, 127) showed that this explanation did not hold good for dynamite, observing that, under certain conditions, only a portion of a 5-grm. charge exploded, the remainder being scattered. This result does not agree with Abel's theory, which shows that the best material for detonating any explosive is itself, because the synchronism of the explosive waves of the detonator and charge is then the most exact.

Experiments carried out by the author with nitro-glycerin, gun-cotton, picric acid, and the German military powder, which is allied to gun-cotton, showed that they all behaved like dynamite, in that they were all bad transmitters of their own explosive effect. The experiments consisted in filling glass tubes (3 mm. bore and 120 mm. long, with one end closed) for about two-thirds their length with the explosive, which was pressed in, and then heating over a Bunsen flame. A violent explosion occurred, shattering the part of the tube heated, but the other part and a considerable portion of the explosive—with gun-cotton more than half—always remained undestroyed. In other experiments the heating was done by a platinum bridge-wire fused into the end of the tube and heated electrically. In these experiments the ends of the tubes were blown off almost without noise and only that portion of the charge surrounding the wire exploded. Picric acid did not explode, but first melted and then commenced to vaporise. When a little fulminate of mercury was placed in the tube and exploded by heating, the picric acid near it also exploded, but more than half was left unaffected. The author thinks that these properties account for explosives burning away quietly when unconfined.

Experiments in which the explosives were heated over a Bunsen flame on a platinum plate are then discussed, and a description of some experiments showing the action of explosives, suitable for lecture demonstrations, given. The author then refers to Max von Förster's experiments (Max von Förster, Comprimierte Schiessbaumwolle, 1886), in which a long lead cylinder with an axial hole was filled evenly with gun-cotton, the latter being fired by a fulminate detonator placed on top. The deformation of the cylinder was less and less from the top towards the other end, which showed that the detonator had a less effect on those portions of the gun-cotton remote from it than on those near it, and consequently the effect of the explosion of the further portions was less. The author believes that the difference between the above-named explosives and others is that the latter are good transmitters of the explosive effect. The duration of the exploding of black powder is much greater than that of quick explosives, and therefore the transmission from part to part takes place more certainly. With nitrogen chlorides, the diazo bodies, and many other violent explosives, the transmitting power is for some unknown reason much greater, and there is no difference between the burning and exploding of them, as there is with the other above-named explosives.—R. B. P.

#### PATENTS.

*Improvements in Non-poisonous Matches.* V. Simonet, Vienna, Austria. Eng. Pat. 17,071, September 11, 1893.

According to this invention the striking ends of the wooden splints are impregnated with a solution of potassium chlorate, "sodium hyposulphite" (thio-sulphate), and gum arabic in

water. Thus prepared, there are no "heads" liable to fall or break off, and the matches ignite easily by friction on a surface of amorphous phosphorus. A further part of this invention consists in imparting a greater degree of inflammability to the composition used for tipping safety matches and those which can be ignited by friction on any rough surface, by adding to the composition a certain quantity of powdered zinc previously triturated with amorphous phosphorus.—W. M.

*Improvements in Methods of Securing the Chemical Stability of Nitro-Compounds.* R. S. Schüpphaus, Brooklyn, U.S.A. Eng. Pat. 22,384, November 22, 1893.

THE object of this invention is to secure the chemical stability of nitro-compounds by the addition of a suitable quantity of urea after the nitro-compounds have been freed from acid as far as possible by washing. The urea is added in the form of a solution in methyl or ethyl alcohol.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*A Recuperative Gas Furnace.* C. Bigot. Monit. Scient. (4) 7, 519—520.

THE gas enters the furnace laterally through a series of Bunsen burners B, each fitted with an independent ferrule. The flame passes between the casing C and the movable piece F, through which and the central tube G it descends. G is fitted with a chimney to produce a strong draught, and is surrounded by a second larger tube H, having at its outer end a controllable air inlet. The air passing along H is heated by contact with G and passes up into the furnace at the point where the flames enter, producing an intense and complete combustion. The joints of the various pieces making up the body of the furnace are made with sand lutes. The consumption of gas is small, and one can work

Fig. 1.

with either a reducing or an oxidising flame, as the air admitted to the furnace is under complete control. The furnace lends itself particularly to ceramic work, the fusion of metals, glass, and enamels, and to the study of limes, cements, &c. The furnace will give temperatures that have never before been attained in laboratory apparatus, save by the use of air under pressure.

The author is particularly engaged on the study of the behaviour of natural clays which, when heated to the temperature at which porcelain is burnt, give the product known as "stoneware." He has been able to prove that they contain a notable quantity of mica in the form of very

Fig. 2.

thin and small flakes intimately mixed with the clay. It appears from his experiments that this mica plays the rôle of a scouring body and permits the clay to undergo that incipient vitrification which characterises "stonewares."

—R. B. P.

*A Drying Oven for Drying in Hydrogen at the Temperature of Boiling Water.* F. W. Morse. Amer. Chem. Soc. 15, 709—710.

THE oven consists of a cylindrical copper box with double bottom and wall; the inside of the oven is seven inches in

diameter and nine inches in depth, space between walls one inch. The hydrogen enters by a brass tube G and passes through a coiled tube between bottom and wall of the oven; this tube then enters the inner oven near the top. The gas is thus heated before entering the drying chamber; W is a water-gauge and S the steam outlet. Drying is accelerated by placing a dish of sulphuric acid on the bottom of the oven, and upon this dish rests a rack to receive the watch glasses or drying dishes. It is well also to have the interior of the oven blackened to increase radiation, and the outer cover plated with nickel. Repeated trials showed differences of not more than 0.2° C. between the temperature of the water and that of the drying chamber. The hydrogen gas passes out of the oven by an outlet not shown. The cover C fits loosely in the copper trough T, and the mercury M makes a perfectly tight joint.—V. C.

## PATENT.

*Improvements in Pyrometers.* E. A. Ueling and A. Steinbart, Birmingham, U.S.A. Eng. Pat. 15,484, August 15, 1893.

If air or gas at constant pressure be made to pass successively through two small apertures, then the pressure

between them will remain constant, provided that the temperature of the fluid passing through each of the diaphragms remains constant. If, therefore, the gas passing through the first aperture vary in temperature, whilst at the other it is kept at a certain normal temperature, then the variation of pressure between the apertures will be a measure of the temperature of the gas as it entered.

The patentees have made use of this principle in constructing their pyrometer, which is represented in the accompanying figure. The air or gas enters the pyrometer at *A* and becomes heated before passing through the first diaphragm *a*. It is then cooled to a constant temperature in passing through the worm *b b*, surrounded by ice or boiling water, and finally passes out into a constant partial vacuum at *d*<sup>1</sup> through the second diaphragm, secured between the couplings *c* and *d*. The constancy of the partial vacuum is ascertained by means of the manometer *e e*<sup>1</sup>, *i* being open to the atmosphere. The variation in pressure of the air between the apertures or diaphragms is registered by the manometer *f f*<sup>1</sup>, which is preferably graduated to read off directly the temperature of the diaphragm *a*, *i.e.*, the temperature it is desired to measure. If the pyrometer is operated by suction, some form of vacuum gauge, such as that represented in the figure, is

all that is necessary, but if it be operated by pressure, then some form of pressure gauge must be substituted for the vacuum gauge.—J. S.

reagents which decompose polysulphides (acids, alkalis, oxygen) destroy the coloration. The reaction is stated to be very delicate.—H. T. P.

*INORGANIC CHEMISTRY.—QUALITATIVE.*

*Test for Free Sulphur.* J. C. Gil. Zeits. anal. Chem.  
1894, 34--55.

A small quantity of an alkaline polysulphide, added to boiling absolute alcohol, imparts to the latter a coloration ranging from pale sky-blue to a deep greenish-blue. This reaction may be utilised for the detection of free sulphur. It is only necessary to boil the substance under examination with strong alcohol containing in solution a little potassium or sodium hydrate. In presence of sulphur the characteristic blue or green colour will be developed. The coloration disappears on cooling, but, in absence of air, is restored on again applying heat. Generally speaking, all

*INORGANIC CHEMISTRY.—*  
*QUANTITATIVE.*

*The Estimation of Phosphorus in Steel containing Silicon, and in Pig-iron.* J. Spüller and S. Kalman. *Zeits. anal. Chem.* **32**, 1893, 538-550.

THE authors find that the phosphorus in steel or iron containing silicon, may be accurately determined by the following modification of the phosphomolybdate method. The sample of iron is dissolved in nitric acid, large excess of the latter being avoided; the nitrous fumes are driven off by heat, a little dilute potassium permanganate solution added, and the solution boiled until the red tint disappears. The precipitated manganese dioxide is then reduced by

10 per cent. potassium nitrite solution, the liquid boiled and subsequently precipitated at 55–60° with molybdate solution. Under these conditions no silicon separates as silicomolybdate, as is the case if ammonium salts be present in any quantity. The phosphomolybdate is filtered through a filter which is partially filled with paper fibres, obtained by treating good filter paper with hydrochloric acid (sp. gr. 1.16), pouring the mass into water, and washing till free from acid. The authors have employed this paper sludge for many years in the filtration of barium sulphate, to prevent the precipitate from going through the filter. Phosphorus determinations made by the above method, in which the ammonium phosphomolybdate was weighed as such in the usual way, compare very favourably with those made by the ordinary magnesium pyrophosphate method.

—W. J. P.

*The Determination of Phosphoric Acid by the Titration of the Phosphomolybdate Precipitate with Standard Alkali.*  
H. Pemberton, jun. Jour. Franklin Inst. 1893, 136, 362–376.

THE solutions required in this method are to be prepared as follows:—

**Ammonium Molybdate.**—Ninety grms. are dissolved in somewhat less than a litre of water, and the clear liquor is decanted; the residue of molybdic acid is dissolved in a little ammonia and added to the bulk of the liquid. If the ammonium molybdate contains traces of  $P_2O_5$ , a few decigrams of magnesium sulphate, and ammonia to faint alkalinity, are added. The solution is now made up to one litre.

**Ammonium Nitrate.**—A saturated aqueous solution.

**Nitric Acid.**—Sp. gr. 1.4.

**Potash Solution.**—This is of such strength that 100 cc. of it will neutralise 32.65 cc. of normal acid. It must be freed from carbonate by barium hydrate, and its strength is best determined by a direct test upon a phosphate solution of known strength, conducted as described below.

**Standard Acid.**—This must be equivalent in strength to the potash solution.

**Phenolphthalein Solution.**—One gram. of phenolphthalein is dissolved in 100 c.c. of 60 per cent. alcohol, and at least 0.5 cc. of this solution is used for each titration.

The analysis is conducted as follows:—One gram. of a phosphate, or 2–3 grms. of a fertiliser, are dissolved in nitric acid, an excess of which can be used with impunity, and the solution made up to 250 cc. The solution need not be evaporated to dryness, nor filtered; the insoluble matter in a phosphate rock rarely exceeds 10 per cent. and its volume is only about 0.05 cc. Twenty-five cc. of the solution are measured into a 4-oz. beaker and neutralised with ammonia—until a precipitate just begins to form—and then treated with 5 cc. of the nitric acid. Ten cc. of the ammonium nitrate solution are added and the whole diluted to 50–75 cc. The solution is now heated until it boils, and 5 cc. of the ammonium molybdate solution added. This is followed by a second and third 5 cc. if necessary. The precipitate is allowed to settle, filtered at once, and washed thoroughly with water by decantation and on the filter. The filter and precipitate are transferred to the beaker, the standard alkali is run in, phenolphthalein added, and the excess of alkali titrated with the standard acid. Each cc. of the alkali is equivalent to one mgrm. of phosphorus pentoxide.

The author shows that the above ratio of alkali to  $P_2O_5$  is correct by quoting experiments which prove that 23 molecular weights of  $Na_2CO_3$  are necessary to neutralise one molecular weight of the yellow phosphomolybdate—

—A. G. B.

*Influence of Free Nitric Acid and of Aqua Regia on the Precipitation of Barium as Sulphate.* P. E. Browning. J. Anal. and Appl. Chem. 1893, 7, 325–330.

THE author's results show that the presence of an excess of nitric acid or aqua regia amounting to 10 per cent. by volume of the liquid treated, is actually beneficial in the estimation of barium as sulphate. Usually the advantage thus gained is observed in the tendency of the precipitate to fall in a coarsely crystalline state, a condition favouring ready and efficient filtration. In certain special cases in which substances such as ammonium nitrate, ammonium citrate, sodium citrate, and metaphosphoric acid, which otherwise would exert solvent action, are present, the precipitation is rendered more complete by adopting the beneficial degree of acidity above suggested. The contaminating effect of such substances when complete precipitation has been brought about, and which thus leads to excessive results, may be corrected by dissolving the precipitate first obtained in concentrated sulphuric acid, and reprecipitating by rapid evaporation, when the precipitate resulting will have assumed the coarsely crystalline condition desired, and will also be freed from the traces of contaminating substances referred to.—A. R. L.

*Quantitative Precipitation in Presence of Hydroxylamine.* P. Janonach and J. Mai. Ber. 1893, 26, 1786–1787.

THE authors find that the presence of hydroxylamine in the solution of a salt exerts an influence on the precipitation of the metallic base by ammonia, thus:—In some cases, precipitates are produced which do not result by the use of ammonia alone; in others, precipitation is completely arrested, or the precipitate itself considerably modified. The following example is cited of the precipitation of chromic hydroxide in presence of hydroxylamine:—Potassium bichromate (about 1 gram.) is dissolved in water (50 cc.) and converted into chromic salt by boiling with alcohol and hydrochloric acid; after evaporating off the alcohol, the liquid is diluted to 300 cc. and hydroxylamine hydrochloride (2 grms.) and an excess of ammonia are added to it while boiling. Precipitation is in this way complete, the excess of ammonia exerting no solvent action on the violet-red precipitate, which can be filtered and washed (without the aid of a suction pump) with much greater ease than can the ordinary chromic hydroxide precipitate. The filtrate is completely colourless, and in it the potassium may be accurately estimated.—A. R. L.

*The Estimation of Hydrocyanic Acid.* G. Gregor. Zeits. Anal. Chem. 1894, 30–45.

THE author has investigated some of the adopted methods for determining hydrocyanic acid in certain medicinal liquids, as, for instance, essence of bitter almonds, laurel-water, &c., and in conclusion recommends the following *modus operandi*.

**Gravimetric Method.**—Fifty cc. of the sample to be examined, contained in a stoppered bottle, are shaken with 5 cc. of ammonia; an excess of silver nitrate (25–30 cc. of decinormal solution) is then added, and the liquid, after shaking, slightly acidified with nitric acid. It is essential that the reagents be added in the order given, and that all the operations be conducted as quickly as possible. The precipitate of silver cyanide is finally collected and weighed in the usual manner.

**Volumetric Method.**—Similar to the above. The liquid, with precipitate, is made up to a definite volume, filtered, and the excess of silver determined in an aliquot part of the filtrate by titration with decinormal potassium thiocyanate solution, using ferrie sulphate as an indicator. The results are stated to be very accurate, and as the presence of alcohol does not influence them, the method may be directly applied to alcoholic preparations containing hydrocyanic acid. Of course, chlorine must be absent, but this is usually the case, since the liquids in question are generally prepared by distillation.—H. T. P.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*A Colour Reaction of Acid Anilides.* J. Tafel. Ber. 25, 112.

THE acid anilides, like the corresponding phenylhydrazones and osazones, yield colour reactions with potassium bichromate or lead peroxide. The test is applied by dissolving a few mgrms. of the anilide in strong sulphuric acid and adding a little powdered potassium bichromate. A red to violet coloration will be developed. The reaction is common to all the simple anilides and phenylcarbamides (with one or two exceptions).—H. T. P.

*The Detection and Estimation of Formaldehyde.* A. Trillat. Bull. Soc. Chim. [5], 9, 305.

See below under Organic, quantitative.

*Detection of "Abrastol" (Calcium  $\beta$ -naphthyl Sulphate) in Wine.* Sanglé-Ferrière. Comptes rend. 1893, 117, 796—797.

THE chemical and therapeutical properties of "abrastol" have been described by Dujardin-Baumetz and Staehler (Bull. gén. de Thérap. Juli 1893). This antiseptic is calcium  $\beta$ -naphthyl sulphate,  $(C_{10}H_7OSO_2)_2Ca$ . It has the advantage over  $\beta$ -naphthol in that it is soluble in an equal quantity of water. It gives, even in a solution containing 0.2 grm. per litre, a beautiful blue coloration with ferric chloride, but this reaction cannot be utilised for its detection in wine. For the latter purpose the author proceeds as follows:—Two hundred cc. of the wine is boiled for an hour in a reflux apparatus with 8 cc. of hydrochloric acid when the abrastol is hydrolysed to  $\beta$ -naphthol, which latter may then be extracted with benzene, and the residue left on distilling the benzene solution taken up with chloroform. A fragment of caustic potash is then dropped into the chloroform solution and it is boiled for two minutes, when a blue coloration is produced, changing to green, and finally becoming yellow. With traces of  $\beta$ -naphthol the solution is slightly greenish and the fragment of potash only is coloured blue. By means of this reaction 0.0625 grm. of  $\beta$ -naphthol (corresponding to 0.1 grm. of abrastol) per litre can be detected. The presence of abrastol in no way vitiates the determination of potassium sulphate by the ordinary method, as the compound is only hydrolysed after prolonged boiling.—A. R. L.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*The Detection and Estimation of Formaldehyde.* A. Trillat. Bull. Soc. Chim. [5] 9, 305.

THE liquid to be examined for formaldehyde is mixed with  $\frac{1}{2}$  cc. of dimethylaniline and a few drops of sulphuric acid, heated for half an hour on the water-bath, then made alkaline and boiled until the odour of dimethylaniline has disappeared. The liquid is filtered, the paper moderately washed, spread out in a porcelain dish, and, after moistening with acetic acid, sprinkled over with powdered peroxide of lead. The presence of formaldehyde is indicated by the development of a blue coloration (due to the formation of tetramethyldiamidodiphenyl carbinol). Another method is based on the fact that formaldehyde yields with aniline a precipitate of anhydroformaldehydaniline  $(C_6H_5N:CH_2)$ . It is only necessary to mix dilute solutions of the two bodies; after some hours a whitish precipitate or turbidity appears. The reaction is very delicate, and allows of the detection of formaldehyde in solutions containing only 1 in 20,000. In this case, however, the turbidity only develops after several days. The reaction is also characteristic for acetaldehyde. For quantitative purposes, 1—1 cc. of the formaldehyde solution to be tested, are added drop by drop to an excess of an aqueous solution of aniline (3:1,000). After 48 hours the precipitate is collected on a tared filter-paper, dried at 40° C., and weighed.—H. T. P.

*The Alkali Test for Kerosene, Naphtha Products, Hydrocarbon Lubricants, &c.* K. Lissenko and A. Stepanow. Dingler's Polyt. J. 290, 139—143.

ABOUT ten years ago endeavours were made in the Russian petroleum districts to economise in the quantity of caustic soda used in the refining of petroleum. Kerosenes were obtained which satisfied the usual tests, but in practice were found unsuitable for lamp oils, as they did not rise freely in the wicks. Investigation proved that this was due to the presence in the kerosene of small quantities of saponaceous salts, and analysis sometimes showed as much as 0.01 grm. ash in 1,000 grms. of kerosene, this ash consisting of  $CaO$ ,  $MgO$ ,  $Fe_2O_3$ ,  $Na_2O$ , and  $SO_3$ . Further investigation proved that for a lamp oil the ash should certainly not exceed 0.01 grm. per 1,000 grms. oil, and that in the best oils, it generally varied between 0.004 and 0.007 grm. The presence of these soaps or salts is equally detrimental in lubricating oils.

As the ash determination is troublesome, and also somewhat uncertain on account of possible loss of sodium salts by volatilisation, the so-called "alkali test" was introduced. Though used in various slight modifications, this consists mainly in mixing in a flask 300 or 500 cc. kerosene with 6 or 10 cc. of a 2 per cent. solution of caustic soda, warming to 60—70°, and shaking the whole violently for five minutes. The mixture is then transferred to a separating funnel, the alkaline extract filtered through a double filter, and acidulated with HCl. The acids in the naphtha and in the saponaceous salts which had been extracted by the alkali are thus precipitated, and the degree of turbidity produced thereby indicates the amount of impurity present in the oil. The turbidity—originally simply roughly stated as satisfactory or the reverse—is now estimated by the size of print which can be read through the opalescent liquid contained in a glass cylinder of given diameter, the operator being required to specify the diameter of the cylinder, and the size of print he can just discern. The kerosenes are now divided into classes according to the results given by this "alkali test." A definitely fixed scale is being constructed, and details will be published next year (1894). Even the best kerosenes give a slight opalescence. The theory of the test is clear, viz., that the soaps and acids present in the oil are dissolved in the dilute alkali, and on acidifying the alkaline extract the acids which are insoluble in water render the extract opalescent. In testing lubricating oils, which generally contain a considerably larger quantity of ash (sometimes as much as 0.125 grm. per 1,000 grms. oil), the test is somewhat modified. In this case 5 cc. of a 1.5 per cent. caustic soda solution is mixed with 10 cc. of the oil, the whole heated to 80°, shaken violently for some time, allowed to stand at 70° for 2 to 3 hours to settle, and then examined. If the aqueous layer is then milky, and there is a more or less considerable precipitate between the aqueous and oil layers, the oil is undoubtedly insufficiently purified. In most cases the aqueous solution is clear, but a more or less marked yellowish red film is seen at the point of contact of the two layers. In such cases, if the ash is small, the oil is a satisfactory lubricating oil. It only very rarely occurs that the oil is so absolutely free from salts and acids as to give no film. Another form of this test sometimes used is to shake the oil to be tested with a small quantity of strong caustic soda solution. If the kerosene is pure the two liquids rapidly separate again with a perfectly bright contact surface. If the kerosene is impure a whitish film forms at the point of contact of the two liquids. This form of test, however, only decides between pure and impure oil, and gives no indication of the degree of impurity.

The view held in Baku and elsewhere of this alkali test was that the alkali dissolved out the soaps (possibly in the form of basic salts), and that the test was a definite proof of the presence or absence of these soaps in the oil. The authors have carefully investigated this matter, and their conclusions (confirmatory in many respects of the work of Doroschenko and of Engler) are as follows. These saponaceous salts are almost absolutely insoluble in pure neutral petroleum, but dissolve readily in the same if it contains a

trace of naphtha acids. Almost all petroleum contains more or less of these acids, which are generally mixtures of hydro-aromatic and sulphonic acids and phenolic compounds. Kerosene, when distilled in the air, or even when shaken at 70–80 with air, generally undergoes slight oxidation with formation of traces of these acid compounds, so that absolutely neutral kerosene is rarely met with. The salts of these naphtha acids undergo partial hydrolysis in the presence of water, and though excess of alkali in some degree prevents this hydrolysis, the latter is not completely stopped till the excess of caustic soda amounts to at least 10 per cent. of the water. Thus, in the purification of petroleum by weak alkali, as now often adopted, and subsequent washing with water, part of the salts first formed becomes again hydrolysed, the acid so liberated is taken up again by the petroleum, and the acid petroleum in its turn re-dissolves some of the salts. The authors therefore believe that for good purification, final treatment with strong caustic alkali should be adopted. The presence of small quantities of these naphtha acids in the oil does not seem to be detrimental as long as no salts are present. From this point of view the alkali test, as at present carried out, is unsatisfactory, as it really only determines the presence or absence of these naphtha acids without deciding whether they are present in the free state alone or also in the form of the detrimental salts. As the ash determination is difficult and not altogether satisfactory, testing for these salts is at present unsatisfactory. The authors suggest as a test which, as far as preliminary trials go, seems to be satisfactory, the shaking of the petroleum to be tested with water containing a few drops of phenolphthalein. If salts are present, hydrolysis takes place and the liberated alkali, being taken up by the water (whilst the acid remains in the oil), colours the solution violet. The aqueous extract may even be titrated. Further investigation of this test is, however, required.—L. T. T.

*Characteristics of Glucose Syrups.* W. E. Stone and C. Dickson. *J. Anal. and Appl. Chem.* 1893, **7**, 317–321.

*Specific Gravity.*—A given weight of the syrup is dissolved in water and the volume made up to 100 cc. The specific gravity of this solution is then ascertained by a Westphal hydrostatic balance. The specific gravity of the syrup may be then calculated with approximate accuracy by the formula  $D = \frac{W}{100 - (w - W)}$  in which W is the weight of syrup, and w the weight of 100 cc. of the solution.

*Water.*—The method adopted consists in mixing a weighed portion of the syrup with weak alcohol and a known weight of clean sand, heating over a water-bath with occasional stirring until dry, adding a quantity (5 cc.) of strong alcohol, evaporating over a water-bath, and finally drying in an air-bath at 100°.

*Ash.*—A beaker containing a sufficient quantity of the syrup and a small pipette are accurately weighed; the pipette is then filled with syrup, and the upper end closed with rubber tubing and a screw pinch-cock. The pipette thus charged is suspended over a weighed platinum dish, which is heated to redness, and the syrup allowed to drop from the pipette into it at such a rate that each drop is carbonised and partially incinerated before its successor falls. When sufficient syrup has been run in, the pipette is returned to the beaker and the whole reweighed. The partially burned mass is extracted with water, the residue incinerated at a high temperature, and the watery extract finally added to it; the whole is then evaporated to dryness and weighed as crude ash.

*Relative Reducing Power.*—The cupric reducing power was found to be considerably augmented after inverting the sample. This was effected by dissolving 5 grms. in 200 cc. of water, adding 10 cc. of concentrated hydrochloric acid, and heating the mixture for half an hour at 60°–70°, neutralising the acid, and diluting to 250 cc. The minimum increase in the reduction after inversion was 0.97, and the maximum 22.76; the syrup which exhibited the larger difference commanded the highest price.

*Specific Rotary Power.*—The determination of this constant in the original syrup, after inverting it, and after fermenting it, furnishes an interesting means of comparison between samples.—A. R. L.

*The Estimation and Separation of the Cacao-Alkaloids.* W. E. Kunze. *Zeits. Anal. Chem.* 1894 [1], 1–29.

In the earlier portion of his paper the author describes and criticises the principal methods employed for the above purpose, and concludes that they are all more or less untrustworthy. In most cases the presence of caffeine appears to be either entirely neglected, the mixture of alkaloids finally obtained being regarded as pure theobromine; or an imperfect means is adopted of separating them (solution of the caffeine in benzene, &c.). Details are then given of experiments made to determine the best mode of operating. The removal of the fat (from cocoa, &c.) by petroleum ether, &c., prior to the extraction of the alkaloids, is not recommended, as the caffeine is partially or wholly dissolved with the fat. Methods in which an aqueous extract of the raw material is evaporated with magnesia, lime, &c., the residue being treated with chloroform, are unsatisfactory, because the mass obstinately retains a large portion of the alkaloids. A similar objection applies when the aqueous extract (after clarification with animal charcoal or compounds of iron and aluminium) is shaken with a solvent. Much of the alkaloid appears to be absorbed or precipitated by the clarifying agent.

As the result of his experience the author has worked out the following method, which he claims to be more accurate and expeditious than any process hitherto published.

1. For the estimation of total alkaloids, the material to be examined is boiled with dilute sulphuric acid (5 per cent.), filtered, and the alkaloids precipitated from the filtrate by a large excess of a nitric acid solution of sodium phosphomolybdate. The precipitate, which settles well, is filtered off after 24 hours, washed with dilute sulphuric acid, and at once decomposed by treatment with baryta water, the excess of barium being removed by carbon dioxide. The liquid (and precipitate) is then evaporated to dryness, and the residue extracted by boiling chloroform. The chloroformic solution on evaporation leaves the alkaloids almost perfectly pure, and containing only a trace of ash.

2. Separation of the alkaloids may be effected with great accuracy by converting the theobromine into the insoluble silver salt. For this purpose the mixture of alkaloids is dissolved in ammonia, a considerable excess of silver nitrate added, and the solution boiled down to a very small bulk, and until all free ammonia is expelled. The crystalline precipitate ( $C_8H_7AgN_3O_2$ ) is collected, washed with boiling water, ignited, and the metallic silver weighed. The process may be made volumetric by titrating the excess of silver in the filtrate by Volhard's method. In the latter case the alkaloids may be readily isolated from the precipitate and filtrate (after titration) and tested as to their purity, identity, &c.—H. T. P.

*The Separation of Volatile Fatty Acids.* M. Wechsler. *Monatsh. f. Chem.* **14**, 462–469.

THE method of partial neutralisation and subsequent distillation was employed by Liebig (*Annalen*, **71**, 355) for isolating butyric acid from a mixture of butyric and isovaleric acids, and further for separating acetic acid when mixed with either of the above acids. In the former case he states that butyric acid distils off, leaving isovaleric acid behind as a salt; whilst in the latter case the acetic acid remains as a salt, and the butyric or isovaleric acid distils over. Vieil (*Annalen*, **148**, 163) finds the opposite result in the case of a mixture of butyric and isovaleric acids, and observes that when the mixture is partially saturated, isovaleric acid distils off, leaving butyric acid behind. Fitz (*Ber.* **11**, 42) and Hecht (*Annalen*, **209**, 319) both state that when a mixture of acetic, butyric, and caproic acids is distilled with steam, the acids of highest

molecular weight come over first. Erlenmeyer and Hell's method (Annalen, 160, 226) consists in fractional saturation with silver carbonate, the acids of highest molecular weight separating first. Barré (Comptes rend. 68, 122) converts the acids into their ethyl ethers, and separates these by fractional distillation, whilst Luck (Zeits. f. analyt. Chem. 10) has devised a method founded on the different solubilities of the barium salts of the acids in alcohol. According to Lieben, Liebig's method is not as accurate as Liebig considered, but a satisfactory separation can be obtained by suitably modifying it, and by partially neutralising the mixture it is always the higher acids which distil off, whereas the lower remain behind as salts. The author, at Professor Lieben's suggestion, has tested the method by applying it to equivalent amounts of mixtures of the following acids:—Formic and acetic, acetic and propionic, acetic and butyric, acetic and isobutyric, propionic and butyric, butyric and caproic acids. In order to separate them the acids are mixed in an aqueous solution with 0.8 of the theoretical amount of alkali, and distilled so long as the distillate is acid. The residue is then decomposed with 0.6 of the theoretical amount of dilute sulphuric acid and again distilled, and finally, after adding more sulphuric acid, the last fifth is distilled off. The first fraction contains the higher and the last the lower acids in an almost pure state. The mixture of butyric and isovaleric acids could not be separated by this method, a result in variance with the statements both of Liebig and of Veil.—T. A. L.

*Valuation of Tallow by Determination of the Solidification Point of its Fatty Acids.* F. Wolfbauer. Mitth. k.k. Tech. Gewerbe-Museums in Wien, 1894, 57—68.

In order to obtain concordant results when different observers examine tallow as regards its "titre," or solidification point of the fatty acids obtained by saponification, &c., it is necessary that a uniform mode of working should be adopted; for this purpose the author modifies "Dalcian's process" as follows. 120 grms. of the tallow to be tested are heated in a beaker to a temperature but little above the melting point, and 45 cc. of caustic potash solution added (sp. gr. 1.509, containing 48 per cent. of KOH); the whole is well stirred until a uniform magma is produced, and then allowed to stand two hours in a chamber at 100°, the beaker being covered with a clock glass, and the whole stirred from time to time. A sample is then tested by warming with 50 per cent. spirit; if a clear solution is produced, the saponification is complete; if not, the heating at 100° is continued until a sample does show a clear solution. 165 cc. of dilute sulphuric acid of sp. gr. 1.113 are then added (or 22 cc. of concentrated acid and 150 of water), and the whole boiled (preferably in a silver dish) until the separated fatty acids are perfectly clear. After cooling (by floating the dish on cold water), the watery fluid is separated, and the fatty acids boiled up with 5 per cent. sulphuric acid solution, and then repeatedly with water to wash out mineral matter. The fatty acids are then dried at 100° for two hours, and transferred to a thin-walled test tube, fitted with and surrounded by a cork, which itself fits into an empty wide-mouthed bottle. A thermometer fitted through a cork into the test tube, is immersed in the fatty acids up to 33°, a bulb being blown on the stem between 2° and 28°, so as to shorten its length by some 26°; stirring is kept up (using the thermometer as a stirrer) until the mass becomes distinctly turbid, showing that incipient solidification has set in; at this stage the thermometer indicates a slight rise. For some minutes a stationary temperature is then registered, the disengagement of latent heat as solidification progresses balancing the loss of heat by radiation, &c. This stationary temperature is the "titre" of the tallow. Duplicate valuations should agree within 0.1° C., the thermometer scale being divided into fifths of a degree; the fatty acids should be tested with alcohol and ammonia to make sure that saponification is complete.

A number of specially made experiments as regards possible sources of error and of want of concordance, yielded the following results. As regards the saponification process, no difference in the titre finally deduced is

observable whether watery or alcoholic caustic potash solution be used, provided that the alcohol be completely washed out from the soap by 1½ hours' boiling with a litre of water; nor does the time of heating affect the result, the same value being obtained in two duplicate experiments, in which the times were respectively 1½ and 15 hours. On the other hand, incomplete removal of water during the drying of the fatty acids tends to lower the titre by some tenths of a degree, as also does the use of a narrower test tube. The size recommended is 35 mm. diameter and 180 long, holding 105 cc. of melted fatty acids when filled to about 10 mm. from the top, requiring fully 120 grms. of tallow. Comparative trials with tubes of this size and of 25 mm. diameter (the lengths being the same) gave values averaging 0.2 lower with the narrower tube; on the other hand, no measurable increment in value was observed with tubes of double width, 70 mm. When the thermometer employed is constructed as above described, so that the quicksilver thread projects but little above the cork of the test tube, the correction requisite for the expansion of the cooler outer portion of the thread is practically inappreciable; but if a thermometer of ordinary construction is employed, so that a considerably longer thread projects, the correction is not negligible, amounting to upwards of 0.1° C.

—C. R. A. W.

*The Methods of Testing Fats and Oils.* E. Millian. Jour. Franklin Inst. 1893, 136, 376—388 and 433—442.

THIS paper has already appeared in this Journal, 1893, 714. There is now added a table (see pages 179 and 180) comprising the constants and characteristics of the vegetable and animal oils and fats.—A. G. B.

*The Determination of Casein in Cows' Milk.* L. L. Slyke, J. Amer. Chem. Soc. 15, 635—645.

THE methods of Hoppe-Seyler and Ritthausen have been commonly employed for determination of casein in cows' milk. The milk is diluted, acetic acid added and precipitation is rendered complete either by warming to 40° C. or by passing carbonic acid through the liquid. The precipitated casein is washed with ether to free it from fat (a tedious operation), dried, and weighed. In the present research, Kjeldahl's method of nitrogen determination was used, a method now much employed in analysis of dairy products. The factor 6.25 is used to convert the nitrogen into casein. In fresh milk 10 grms. are diluted to 100 c.c. at about 41° C., and 1.5 cc. of a 10 per cent. solution of acetic acid is added. Stir and let stand three to five minutes. Decant on filter, wash a few times with cold water. If filtrate not clear, re-filter. The washed precipitate and filter paper are digested as in the Kjeldahl method. In old milk, which shows a marked development of lactic acid, the author finds that the results of casein determination are only approximate. Milk may, however, be preserved from the development of lactic acid, so that the casein may be determined after standing some days, if one part of finely-powdered mercuric chloride is added to 2,000 parts of milk.—V. C.

ANALYTICAL AND SCIENTIFIC NOTES.

*The Diffusibility of certain Gases through Caoutchouc Membranes.* A. Reyher. Bull. Soc. Chim. [3] 9, 404.

ACCORDING to the author, Pietet's observation that sulphur and carbon dioxides diffuse more rapidly than other gases through a caoutchouc membrane, must be referred to an occlusion phenomenon. These gases have a strong affinity for caoutchouc and are rapidly absorbed by one side of the membrane and as rapidly exhaled by the other side. The true diffusion process is said to proceed more slowly.

—H. T. P.

## New Books.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie, mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1893. Erste Halbjahr. Zweite Hälfte. Berlin: R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, Schönebergerstrasse 26, S.W. London: H. Grevel and Co., 33, King Street, Covent Garden.

THE second issue for the first half of 1893. It contains 158 pages of well-illustrated subject matter. The following are the groups of Chemical-technological subjects treated of in the volume:—Food-stuffs. Paper Photography and its Applications. Residuals and their Treatment. Refuse Matters. Manures. Disinfection and Sanitation. Soaps. Explosives. Preparation and Purification of Chemicals. Chemical Analysis. Apparatus. Machinery. Electro-technology and Thermo-technology. Appendix, treating of Adulterations of Trade Products, &c. New Books.

HANDWÖRTERBUCH DER PHARMACIE. Herausgegeben von A. BRESTOWSKI. Wien und Leipzig: Wilhelm Braumüller. K.U.K. Hof- und Universitäts Buchhändler. 1893. London: H. Grevel and Co., 33, King Street, Covent Garden.

VOLUME II. of Brestowski's Dictionary of Pharmacy commences with Parts 13 and 14 of the entire work. These numbers have now been issued. Part 13 commences under the letter L, with "Lab," a secretion in the juices of the stomachs of mammals, and ends with "Magnesium"; whilst Part 14 commences with "Magnesium Acetate" and ends with a monograph on "Mineral Waters," which is to be continued in Part 15.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### NEW CUSTOMS LAW OF THE ARGENTINE REPUBLIC.

The following is a statement of some of the rates of duty leviable under the new law:—

All goods imported from abroad for consumption in the Argentine Republic will pay a duty of 25 per cent., with the exception of the following, which pay as follows:—

40 per cent.—Dry gelatin plates of bromide of silver.

5 per cent.—Fire-bricks; soda-ash, specially intended for use in the industries of the country; nitrate of soda; sulphur, unpurified; and sulphate of lime.

The following will pay specific duties:—

Articles.	Rates of Duty.	
Starch.....	Kilo.	Dols. 0·025
Vegetable oils.....	"	0·12
Sugar, unrefined.....	"	0·003
" refined.....	"	0·07

Articles.	Rates of Duty.	
Candles, stearine or paraffin.....	Kilo.	Dols. 0·15
Chocolate.....	"	0·60
Copper ingots.....	"	0·20
" sheets.....	"	0·10
Drugs used for curing sheep scabs.....	"	0·0125
Tin.....	"	0·02
Pecula.....	"	0·0075
Glycerin, less than 30°.....	"	0·02
Lead.....	"	0·015
Salt, common.....	Hectolitre	0·20
" fine.....	100 kilos.	2·00
Stearine.....	Kilo.	0·14
Zinc, ingots and bars.....	10 kilos.	0·05

The following articles will be free of duty:—Pasteur filters; fulminate for dynamite; fuses for mines; hops; mercury; naphtha, petroleum, impure; pulp for paper making; gunpowder for mines.

#### SWITZERLAND.

##### Customs Decisions.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9  $\frac{6}{10}$  d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the months of October, November, and December last:—

Anhydrous ammoniac, chlorine, oxygen, sulphurous acid, compressed, liquid, in receptacles of wrought iron.—Category 74, duty 2 francs per quintal.

In categories 479 to 481 and 484 the weight of 180 grms. per square metre is considered as the limit between paper of two or more layers and cardboard paper, in the sense that the products weighing up to 180 grms. are still classified as paper, while those exceeding a weight of 180 grms. pay duty as cardboard paper.

#### FRANCE.

##### Customs Decisions.

Note.—Kilo. = 2·204 lb. avoirdupois. Franc = 9  $\frac{6}{10}$  d.

The following decisions affecting the classification of articles in the French Customs tariff have recently been given by the French Customs authorities:—

An alloy of copper, zinc, and a small proportion of manganese and of iron, known under the name of "Delta metal," pays duty as copper alloyed with zinc, raw or manufactured, as the case may be.

Nitro-naphthalene.—Category 280, 2nd paragraph. Duty 15 francs per 100 kilos.

Artificial essences of rum, cognac, &c., or of fruits consisting of alcoholic solutions of ether still containing alcohol, are classified as chemical products not distinguished with an alcoholic base. (Category 282, 1st paragraph.) Under this category they pay the Customs duty of 80 frs. and the interior consumption tax (156·26 frs.) on the proportion of alcohol which they contain.

Carbolic soap is dutiable at 80 centimes or 60 centimes per kilo. net.

Soaps and other products with a basis of pine extract are prohibited from being imported. (Category 316, 2nd paragraph.)

#### UNITED STATES.

##### Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of

articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the Customs authorities in that country.

White fusible enamel, to be used in the manufacture of watches, is dutiable as fusible enamel at 45 per cent. *ad val.* under paragraph 122.

White enamel, cylindrical in form, one-eighth of an inch in diameter, fusible, and commonly used by jewellers in the manufacture of sleeve buttons, watch dials, clock faces, and for other purposes, is dutiable at 45 per cent. *ad val.* under the provision in paragraph 122 for fusible enamel.

Certain "marine oil," a combination of rape-seed oil, cotton-seed oil, low-grade olive oil, and possibly some other expressed oils, prepared after a secret formula and imported for use in the manufacture of marine lubricating oil by blending it with a certain domestic mineral oil, the name of which is not divulged, is dutiable as rape-seed oil at 10 cents per gallon.

Crude eosine, one of the so-called resorcinol colours and a coal-tar preparation, chemical compound, and a coal-tar colour or dye, is dutiable at 35 per cent. *ad val.* under the provisions of paragraph 18 N.T.

Sodium salicylate powder, a medicinal preparation not containing alcohol, and in the preparation of which alcohol is not used, is dutiable at 25 per cent. under paragraph 75.

Ether butyric is dutiable at 2.50 dollars per pound, as a fruit ether or essence under paragraph 25 N.T.

Sodium benzoate, a medicinal preparation not containing alcohol, and in the preparation of which alcohol is not used, is dutiable at 25 per cent. under paragraph 75 N.T.

#### BOUNTIES ON THE MANUFACTURE OF SHALE OILS FOR LIGHTING PURPOSES IN FRANCE.

Lord Dufferin, Her Majesty's Ambassador at Paris, in a despatch to the Foreign Office, dated the 8th January, encloses copy of a French law granting bounties on the manufacture of shale oils for lighting purposes.

This law provides that, dating from the 12th July 1893, and for a period of six years, there will be allowed to the extractors of bituminous schist, intended for the manufacture of shale oils for lighting, bounties to an amount not exceeding 300,000 francs annually, and fixed according to the proportional quantities of raw oils manufactured, without in any case the bounty exceeding three francs per hectolitre of raw oil.

Further regulations will determine the conditions for the application of the law.

Any person proved guilty of fraud or attempted fraud in connection with the obtaining of a bounty will be debarred from benefiting by the bounty and will be liable to the penalties provided in Art. 423 of the penal code.

#### GENERAL TRADE NOTES.

##### PROPOSED CHANGES IN THE UNITED STATES PATENT LAW.

House Bill No. 5,014, now under consideration by the Committee on Patents of the House of Representatives, contains some new provisions affecting holders of patents. The important sections of the Bill are the following:—

"No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid by reason of its having been patented or caused to be patented in a foreign country less than two years prior to the application for a patent on the same invention in this country, but every such patent hereafter granted shall be limited in duration to the term of 17 years from the time when the earliest foreign patent commences to run.

"That section 4921 of the Revised Statutes be amended by adding the following: but hereafter, whenever a patent is alleged to be infringed, patentee or his representative shall seek remedy by bringing suit against manufacturer or vendor of the article alleged to infringe said patent, and shall in no case bring suit against any individual

who shall have purchased, in good faith, article of a regular dealer in the open market for his own use until the patent has been sustained by the court; provided, that such individual purchaser shall give to patentee or his representative, at his request, the name and residence of the party from whom said article was purchased; and where the damage so claimed is less than 50 dollars, plaintiff shall pay costs of suits of both defendant and plaintiff; and, provided also that this exemption from liability of individual purchasers shall not apply to any corporation or party as to any patented machine or process made or used by them. Actions at law or suits in equity for infringements of patent rights may be brought where the infringement occurs, whether defendant be domiciled therein or elsewhere."—*Engineering and Mining Journal*.

#### THE NEW YORK DRUG TRADE AND THE TARIFF.

The Drug Trade Section of the New York Board of Trade have unanimously decided to present to the Senate and House of Representatives, a memorial containing certain recommendations for amendment of the proposed new tariff bill in the schedules which affect the drug trade. It is recommended that specific duties in preference to *ad valorem* duties be levied, wherever practicable, upon articles pertaining to the drug and chemical trade, because, as these articles are imported in comparatively small quantities, the argument about false weighing does not apply, and the experience of many years proves that specific duties favour the importation of purer and higher grades of drugs, while *ad valorem* duties induce false invoicing by dishonest parties.—*Chemist and Druggist*.

#### THE DENATURING OF ALCOHOL IN GERMANY.

In the course of the debate in the Reichstag on the credits for the Ministry of Home Affairs, the socialist deputy Wurm, who is himself a chemist, asked that the Inland Revenue authorities should adopt a method of denaturing alcohol which would be less injurious to the health of the men engaged in the work. The director of the Board of Health admitted the fact of the noxiousness of the pyridine process, and regretted it, but pointed out that in spite of much experimenting no less physically injurious and otherwise satisfactory process had yet been discovered.—*Ibid*.

#### THE EXPORTATION OF TINCTURES.

In a general order (No. 3, 1894) dated February 10, and issued from Somerset House, it is ordered that tinctures made by licensed rectifiers and compounders may be exported on drawback, by weight or by measure, in iron drums ranging in size from 2 to 10 gallons, and that such drums need not be packed in cases. The tinctures may also be exported by weight or by measure, in earthenware jars ranging in size from 1 to 5 gallons, provided the jars be placed in cases. It is also ordered that no case of tinctures exported in bond shall contain less than 2 gallons, and that any internal package larger than half a gallon shall contain not less than 1 gallon, 2 gallons, &c., or 8 lb., 16 lb., &c. Decimal fractions are to be shown in the schedule of the notice when the exportation is according to weight. The weight per gallon and the bulk quantity should be shown in two decimal places, and the proof to three decimal places. When the weight per gallon as ascertained in the laboratory, taking the average as in the case of strengths, does not exceed the declared weight by more than  $\frac{1}{16}$  lb., the declared weight may be passed as correct. If the average excess is greater, special directions as to the basis of calculation will be issued by the board. When tinctures are exported by measure, officers are to check the contents of bottles by seeing not fewer than one in twenty emptied into a suitable and stamped imperial measure provided by the exporter, and if jars or drums be used, one in every five must be checked. If the exportation be conducted by weight, the quantity in the bottles, jars, or drums, must be checked in the same proportions by measure or by weight, at the exporter's option. Drawback will in future be allowed on toilet vinegars and waters, dentifrices, hair washes, and

brilliantines, according to the quantity of proof spirits present, whether the strength can be ascertained by the hydrometer or not.—*Ibid.*

#### PRODUCTION OF LIME JUICES AND CITRIC ACID.

*Galbraith. J. Anal. and Appl. Chem.* 1893, 7, 310—314.

The lime industry is carried on in a more systematic manner in Montserrat than in any other islands of this group; indeed, the area in Montserrat now under cultivation is about 1,200 acres, of which about 900 acres contain fruit-bearing trees. There is a considerable quantity of lime juice manufactured in Dominica, but there the orchards are smaller, and, with one or two exceptions, the same care is not bestowed in the cultivation of the trees and the manufacture of the juice. The industry is, however, growing, and if the Government succeeds in making roads through the island, it is anticipated that there will be a large increase in the cultivation of the trees. The few trees scattered over the islands of Antigua and St. Christopher suffice only to supply the inhabitants with fruit for their own use. (See this Journal, 1892, 783.)

The fruit begins to ripen in June, when the harvest commences, and reaches its height in August.

Each orchard (in full bearing) yields an annual average of 60—80 barrels per acre, which it is thought could be augmented by careful cultivation and manuring. A barrel of fruit yields from six to eight gallons of juice, containing 12 to 15 oz. of citric acid per gallon. No efficient remedy has yet been found for blight, which causes much trouble and materially affects the yield of fruit.

The exported produce from a lime plantation is: "raw" and "concentrated" lime juice, green and pickled limes, and essential oil. "Raw" lime juice is simply the juice from good, sound, ripe fruit carefully preserved in casks. For the best quality the limes are crushed between the rollers of a mill, old cane mills being usually employed. Most of the raw juice comes to the English market. In the manufacture of concentrated lime juice the fruits are not selected; on the contrary, the fruits which are unfit for manufacturing "raw" juice are made into "concentrated" juice. The process consists in boiling the juice in open pans until it is reduced to about one-tenth its volume: it is then a black viscid fluid containing 80—100 oz. of citric acid per gallon. The concentrated juice is shipped in second-hand beer casks principally to the New York market.

The small quantity which is shipped of green limes goes to the English market; the fruit is carefully selected, wrapped in paper, and packed in crates.

A small quantity of sound ripe limes are also treated with strong brine in casks, which are closed and rendered airtight, and exported: limes preserved in this manner are invariably sent to Boston.

Essential oil is of two kinds: the hand-made, which is the most valuable, and that prepared by distillation. The common mode of extracting this oil from the lime consists in the use of a shallow concave metal plate shaped like an ordinary saucer, in which are studded a number of blunt copper spikes, from the centre of which there is a tube into which the oil runs as it escapes from the rind of the fruit. The tube serves as a handle, and the lime fruit is gently and quickly rolled over the blunt copper spikes until all the oil sacs are burst and the oil escapes and runs into the tube. When full, the tube is emptied into bottles and securely corked. The bottles are allowed to remain until the water and other impurities settle, when the oil is carefully drawn off, filtered, and run into tinued copper vessels for export. Most of the oil exported from Dominica is manufactured by distillation; it is chiefly employed for scenting soaps, and in the manufacture of common essences and perfumes.

The price of the products is about the same in both England and the United States (New York). The average annual shipments from Montserrat for the last five years are as follows:—Raw lime juice, 800 puncheons (120 gallons each); concentrated juice, 200 casks (54 gallons each); green limes, 1,000 boxes; pickled limes, 300 barrels; essential oil, 2,500 pounds.—A. R. L.

#### MINERAL PRODUCTION OF THE UNITED STATES.

The annual report upon the mineral resources of the United States for the calendar year 1892 to the Chief of the Division of Mining Statistics and Technology of the Geological Survey is issued. The summary shows the total value of the mineral products of the country for that year to have been 137,075,176¢, the highest ever known. The following table gives the amount of the production of the several more important articles:—

Products.		Quantities.
Lead.....	Tons	213,262
Zinc.....	"	87,260
Quicksilver.....	Flasks	27,993
Petroleum.....	Barrels	50,509,136
Lime.....	"	65,000,000
Cement.....	"	8,758,621
Salt.....	"	11,998,890
Phosphate rock.....	Tons	681,571
Mineral waters.....	Gallons sold	21,876,604
Zinc, white.....	Tons	27,500
Potters' clay.....	"	420,000

—*Chemical Trade Journal.*

#### COAL DUST IN MINES.

A blue book has been issued, containing a report made by Mr. Henry Hall, one of Her Majesty's Inspectors of Mines, to the Royal Commission on Explosions from Coal Dust in Mines, giving the result of a series of experiments made with coal dust collected from the principal seams in various mining districts. Altogether 52 samples were received, and (with the exception of four or five) all were tested in a mine shaft placed at Mr. Hall's disposal by the proprietors of the White Moss Colliery, Skelmersdale, a wrought-iron cannon being used for the gunpowder shots. Mr. Hall says that the phenomena presented by these experiments as they progressed, and a careful examination of the detailed results, warrant the following conclusions:—

(1) That the flame from a blowing-out gunpowder shot in the presence of dry coal dust always ignites more or less of such dust, and so increases the burning and charring effects of the shot; (2) that when a large flame, such as that of a blowing-out gunpowder shot, or the flame from the ignition of a small quantity of firedamp, traverses an atmosphere containing a very moderate quantity of dry coal dust, the dusty atmosphere will explode with great violence, and the explosion will continue on and pass throughout any length of such atmosphere, its violence and force increasing as it progresses; (3) that coal dust from several seams in different districts, notably those from Glamorgan, Monmouth, Durham, Lancashire, Yorkshire, and Scotland, are almost as sensitive to explosion as gunpowder itself; (4) that coal dust is, as a rule, more sensitive to explosion in proportion to its high quality and freedom from impurities; (5) that a ready supply of oxygen, such as is supplied by a brisk ventilation, has the effect of making coal dust explosions more probable and more severe; (6) that certain "high explosives" are incapable of igniting or exploding coal dust. Of the whole of the dusts tested, that from the Allion Colliery, Glamorgan (Aberdare or Merthyr 4-ft. seam or upper 4 ft.), excelled all others in violence and sensitiveness to explosion, and this seam has the worst history of any in the kingdom, upwards of 1,600 persons having been killed in it by explosions since the year 1845. It was also evident from the experiments that the higher the quality of the coal seam the more liability there is to explosions of dust. With regard to precautionary measures to be taken in the face of these facts, Mr. Hall urges the total abolition of gunpowder from coal mines, and the substitution of

certain "high explosives." Many of the largest firms in the country have, he says, already of their own motion taken this step.—*Ibid.*

#### INTERNATIONAL STANDARDS FOR THE ANALYSIS OF IRON AND STEEL.

The Sub-Committee on Methods, the composition of which is given below, has just issued its bulletin No. 1, from which we take the following statements concerning its organisation and proposed work:—

At the World's Congress of Chemists, in Chicago, last August, following the papers of Professor J. W. Langley, "On the Work of the Committee on International Standards for the Analysis of Iron and Steel," and of Dr. C. B. Dudley, "On the Need of Standard Methods for the Analysis of Iron and Steel with some Proposed Standard Methods," was a brief discussion, which resulted in the reference by that body of the whole subject of standard methods for the analysis of iron and steel, to the Committee on International Standards for Analysis of Iron and Steel. That committee, it will be remembered, consists of seven chemists, in each of five different countries, namely, England, France, Germany, Sweden, and the United States. The American Committee was appointed jointly by the American Society of Civil Engineers and the University of Michigan, with Professor J. W. Langley, Case School of Science, Cleveland, Ohio, as chairman. The other members of that committee were W. P. Barba, Midvale Steel Works, Nicetown, Philadelphia; A. A. Blair, Philadelphia; Professor Regis Chauvenet, President, State School of Mines, Golden, Col.; Professor T. M. Drown, Massachusetts Institute of Technology, Boston; Dr. C. B. Dudley, Chemist, Pennsylvania Railroad, Altoona, Pa.; and Porter W. Shimer, Easton, Pa.

Following the reference of the subject to this committee, it was decided, after consultation, to appoint a sub-committee to take up the question of standard methods. The sub-committee is constituted as follows:—W. P. Barba, A. A. Blair, T. M. Drown, Porter W. Shimer, and C. B. Dudley, chairman. The sub-committee held an organising meeting at the office of A. A. Blair, Philadelphia, on December 13th, all the members being present. The object of the meeting was to map out the work. It was agreed as follows:—

First.—That Mr. Blair should submit a form of circular to go to the iron and steel chemists of the country, asking for a brief outline of the methods which they prefer, and the reasons for all the important points of their methods.

Second.—That the work of the committee should comprehend the recommendation of standard methods to be used as the basis of commercial transactions, and when any of these methods could not be used in steel works in daily practice, on account of time required, an alternative rapid method should be recommended, and its limitations defined.

Third.—That the members of the committee should draw up each proposed standard method in writing, with some minuteness, and give the reasons for each important point, these written drafts to be sent to the chairman, to be duplicated, and sent to every member of the committee. Later, the points agreed upon are to be edited by some one member of the committee.

Fourth.—That only one element should be embraced in a method.

Fifth.—That the first method to be taken up should be phosphorus in steel.

Sixth.—Mr. Barber offered to furnish to each member of the committee, a suitable quantity, not less than a pound or so, of borings of three different kinds of steel, namely one of from 0.01 to 0.02 phosphorus, carbon about 0.90, and silicon about 0.40; another with phosphorus not far from 0.06, carbon 0.50 to 0.60, silicon 0.25 to 0.30, and arsenic 0.15 per cent. The above two to be crucible steel. Another sample of open-hearth steel of carbon 0.90 to 1.05, phosphorus 0.02 to 0.04, manganese 0.30 to 0.40, silicon 0.26 to 0.25, sulphur 0.02 to 0.04, and copper anywhere below 0.10.

Seventh.—Dr. Dudley offered to furnish to each member of the committee, a like amount of borings from a sample

of Bessemer steel of from 0.10 to 0.12 phosphorus, carbon about 0.50, manganese 0.80 to 1.00, silicon 0.02 to 0.05, sulphur 0.07 to 0.10, and copper from 0.07 to 0.10. These samples of steel to be used in deciding various questions that may come up in regard to proposed methods.—*Engineering and Mining Journal.*

Besides the above, drugs to the value of 75,522*l.* were imported, as against 80,151*l.* in January 1893.

## IMPORTS OF CHEMICALS AND DYE-STUFFS FOR MONTH ENDING 31ST JANUARY.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
Alkali..... Cwt.	2,205	6,898	£ 1,982	£ 5,682
Bark (tanners', &c.) "	9,951	19,324	3,388	6,500
Brimstone..... "	30,204	55,815	7,067	11,854
Chemicals..... Value £	..	..	98,594	137,047
Cochineal ..... Cwt.	577	804	3,416	4,729
Cutch and gambier Tons	1,479	2,322	32,211	48,216
Dyes:—				
Aniline ..... Value £	..	..	12,168	19,640
Alizarin ..... "	..	..	13,726	27,572
Other ..... "	..	..	741	882
Indigo ..... Cwt.	21,945	13,936	481,267	296,140
Nitrate of potash . "	15,027	16,281	13,358	15,458
Valonia ..... Tons	2,573	1,836	38,285	24,822
Other articles... Value £	..	..	105,542	164,200
Total value of chemicals	..	..	812,283	763,042

## EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH ENDING 31ST JANUARY.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
Gunpowder..... Lb.	738,300	606,700	£ 19,269	£ 12,825
Military stores.. Value £	..	..	73,981	60,059
Candles..... Lb.	1,459,600	1,620,200	26,196	29,024
Caoutchouc ..... Value £	..	..	92,333	91,745
Cement..... Tons	22,974	27,030	41,269	44,110

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

1135. B. G. Martin and M. J. McMullin. Improvements in filtering plant for the purification of water or other fluids. January 18.

1136. J. E. Carroll. An improved process for purifying water and other liquids, and improvements in apparatus for eliminating soluble salts therefrom. January 18.

1303. S. Trivick, C. J. A. Head, and P. A. J. Head. Improvements in reversing regenerative furnaces for metallurgical and other purposes. January 20.

1347. R. W. B. Creeke. Improvements in and relating to destructor furnaces. January 22.

1377. C. Morel and A. Heimpel. Apparatus for crushing dry or wet materials, such as cements, lime, plaster, alabaster, kaolin, quartz, phosphates, minerals, &c. Complete Specification. Filed January 22. Date applied for August 8, 1893, being date of application in France.

1703. W. Ramsbottom. Improvement in filters specially designed for treating sewage or other fouled waters. January 26.

1790. D. Stewart. See Class XVI.

1866. O. Hamilton. A new or improved drying apparatus. January 29.

2085. J. J. Meldrum and T. F. Meldrum. Condensers. January 31.

2230. T. Drost. An improved centrifugalling process and apparatus therefor. February 1.

2588. J. Nagel. Apparatus for distilling and sterilising water. Complete Specification. February 6.

2915. D. Wickham. Improved apparatus for measuring still or gaseous liquids. February 9.

2944. R. A. Grosse. Improvements in toluol thermometers. February 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1893.

2547. D. H. Lyon.—From D. Hanna. An improved process for separating impurities from water introduced into a boiler, and apparatus therefor. February 7.

4421. G. W. Elliott. Improvements in centrifugal hydro-extractors. January 31.

5375. J. Wetter.—From M. Weinrich. Improvements in the manufacture or restoration of filtering media. January 24.

6243. C. K. Mills.—From A. Costadan. An improved joint for steam, water, gas, and other liquids or fluids. February 7.

6316. H. J. Worssam. Improvements in refrigerators for cooling and evaporating liquids, such as are used in breweries and distilleries, and for such like purposes. January 31.

6408. J. F. Jones. Improvements in apparatus for cooling or heating air or other gases. January 31.

13,929. A. Müller. An improved valve for gases and liquids under high pressure. January 24.

15,488. J. V. Smith. Improvements in method of and apparatus for promoting consumption of fuel. January 24.  
20,549. C. W. Davis. Improved apparatus for mixing or sifting moist or dry powders. January 31.

21,850. H. A. Naber. Improvements in voltmeters. January 24.

23,045. R. Haddan—From F. D. Cummer. Improvements in and connected with the process of and machinery for the drying or heating of gypsum clay, sand, grain, slaughter-house refuse, and other materials. January 31.

23,367. L. Wagner and J. Marr. See Class XVII.

24,165. E. Stern. A new method of closing receivers charged with compressed or liquefied gases. January 24.

## II.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

999. J. H. Lee. Improvements in method of and apparatus for supplying air richer in oxygen than atmospheric air to steam boiler and other furnaces, and for separating and collecting air richer in oxygen on the one hand and in nitrogen on the other, for the various purposes to which air rich in these qualities may be supplied. January 16.

1029. G. St. J. Kueller. Artistically-shaped fuel for use with every kind of gas fires. Complete Specification. January 17.

1188. S. C. Hitchcock. An improved mineral oil. January 19.

1190. F. McNamee. Improvements in the method of and connected with apparatus for drying peat for fuel, litter, or similar use or purposes. January 19.

1231. F. B. Hill and R. D. Brett. Improvements relating to the burning of hydrocarbons for heating and lighting purposes, and to apparatus therefor. January 19.

1238. D. Hancock, J. B. Craig, and A. H. Hancock. Improvements in or relating to the employment of air for lighting and heating purposes. January 19.

1409. S. Williams. An improvement in candles. January 23.

1485. T. H. Jones. Improvements relating to the carbonising of wood for the production of charcoal, and in the utilisation of the products given off in the process of carbonisation. January 23.

1486. W. B. Hartridge. Improvements in and relating to the manufacture of fuel and to apparatus therefor. January 23.

1490. J. Galletly and H. Armour. Improvements in the manufacture of gas from mineral oils, and in the apparatus employed therefor. January 23.

1540. J. Foss. Condenser of noxious vapours from illuminants. January 24.

1653. A. McLean. Improvements in the treatment of peat. January 25.

1659. C. C. Walker. Improvements in apparatus to be used in the purification of coal-gas or for analogous operations. January 25.

1690. B. H. Thwaite and G. Threlfall. Improvements in methods and apparatus for generating gaseous fuel from solid hydrocarbonaceous or carbonaceous material. Complete Specification. January 26.

1833. H. J. Reid. Improvements in the manufacture of briquettes and patent fuel, and in means and apparatus employed therefor. January 27.

1856. J. H. R. Dinsmore. Improvements in the manufacture of illuminating gas. January 29.

1991. A. J. Boulton—From W. A. Koneman and A. F. Hatch, United States. Process of and apparatus for utilising producer-gas as fuel for calcining limestone. Complete Specification. January 30.

2426. F. H. Bacon and B. Donkin. Improvements in and appertaining to the purification of coal or other gases, and apparatus used therein. February 3.

2488. C. J. Yarnold. Improvements in the method and apparatus employed in the production of ozone. February 5.

2554. D. Young. The production or recovery of coal dust for foundry purposes and the machinery or apparatus therefor. February 6.

2630. J. Swallow, C. West, and A. R. Armitage. Improvements in or relating to the treatments of paraffin and other oils for rendering it or them odourless, smokeless, miscible, and non-explosive. February 6.

2702. T. de Zebrowski. A new or improved manufacture of briquettes or artificial fuel blocks. February 7.

2786. B. Bone. Chalk fuel. February 8.

2914. V. B. Lewes. Improvements in and in apparatus for the manufacture or production of gas. February 9.

2937. M. Graham. Improvements in and apparatus for charging inclined gas retorts. February 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

2247. J. C. W. Stanley. Improvements in or relating to the manufacture or production of block fuel, gas, and other useful products from refuse materials. January 31.

3554. T. A. Dillon. An improved method of preparing peat for heating, gas generating, and other purposes. January 24.

3815. J. R. Paisley. An improvement in apparatus for the manufacture of water-gas. February 7.

5920. F. Beale and T. F. Ennis. Improvements in apparatus for charging gas retorts. January 31.

5951. J. H. Fitzgerald. Improvements in gas washers and scrubbers. January 31.

6051. G. de Verna. Improvements in the manufacture of illuminating gas, artificial fuel blocks, and coke for metallurgical purposes. January 31.

6259. G. S. Ellis and A. M. Dolton. Improvements in the manufacture of coal briquettes. January 31.

6506. W. Cross. Improvements in anti-dip valves, employed in the manufacture of gas. January 31.

14,783. F. S. Cripps. Improvements in washers for the extraction of tar, ammonia, carbonic acid, and sulphuretted hydrogen from coal-gas. February 14.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

### COMPLETE SPECIFICATION ACCEPTED.

1893.

5856. C. D. Abel—From F. von Heyden. Process for producing esters from fatty acids with creosote, guajacol, or creosol. January 31.

## IV.—COLOURING MATTERS AND DYES.

### APPLICATIONS.

881. J. B. Boyle and E. Fatta. Perfumed writing and printing ink. January 15.

973. H. E. Newton—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of anthraquinone derivatives. January 16.

974. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring matters derived from anthraquinone. January 16.

975. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of trihydroxyanthraquinones. January 16.

1063. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of  $\beta_1$ -naphthol,  $\alpha_1\beta_1$ -disulpho acid, and  $\beta_1$ -naphthylamine,  $\alpha_1\beta_1$ -disulpho acid. January 17.

1227. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of  $\alpha_1$ -,  $\alpha_1$ -dihydroxynaphthalene- $\alpha$ -monosulpho acid. January 19.

1228. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of acid compounds derived from gallic acid, its anhydrides, or analogous products. January 19.

1229. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of dyestuffs by means of trihydroxynaphthalene monosulpho acid. January 19.

1555. H. Loesner. Manufacture of azoxy compounds of the series. January 24.

1556. H. Schultze. An improved process for the pro-alexyphosphoric acid and of gallic dyeing prepared therefrom. January 24.

1557. J. W. Johnson.—From Kalle and Co., Germany. Improvements in the manufacture and production of new dyestuffs. January 25.

1558. S. Pitt.—From L. Cassella and Co., Germany. The production of perichloronaphthol disulpho acid and disazo dyestuffs therefrom. January 29.

2113. A. W. Gilbody. The manufacture of a new base and the production of dyestuffs therefrom. January 31.

2206. H. Loesner. Improvements in the manufacture of ortho-nitro-toluene, meta- and para-azoxyltoluene, meta- and para-toluidin. February 1.

2232. W. G. Thompson and I. Moore. Improvements in the manufacture of a diamido base and of tetrazo colouring matters derived therefrom. Complete Specification. February 1.

2324. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring matters. February 2.

2325. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of hydroxyanthraquinone-quinolines. February 2.

2503. Read, Holliday and Sons, Lim., and K. B. Elbel. The manufacture of a bluish-red dye belonging to the rosinduline series. February 5.

2504. Read, Holliday and Sons, Lim., and K. B. Elbel. Improvements in the manufacture of azo-colouring matters. February 5.

2591. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of dyestuffs. February 6.

2592. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The production of azo-colouring matters upon fibres. February 6.

2758. J. Altschul. Manufacture and production of a new diazo-compound for use in dyeing and printing. February 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4979. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture and production of sulpho-acids of the naphthalene series, and of colouring matters obtainable therefrom. January 31.

5141. S. Pitt.—From L. Cassella and Co. Improvement in the production of disazo dyestuffs from  $\gamma$  amidonaphthol sulpho acid. January 24.

5690. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brünig. Production of colouring matters. January 24.

5691. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brünig. Manufacture of acid colouring matters, being the sulphonic acids of alkyl derivatives of the diamidodiphenyl-metatoxy-carbinol. January 31.

5692. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brünig. Manufacture of thionine colouring matters dyeing on mordants. January 24.

6249. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Improvements in the manufacture of auramine. January 31.

7181. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of a new blue colouring matter. February 14.

7182. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of new alizarin dyestuffs. February 14.

7185. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brünig. Manufacture of colouring matters. February 14.

7187. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brünig. Manufacture of a novel diamido base, and of colouring matters from the same. February 14.

7263. C. Blaneau. A liquid metallic composition for use as a writing or printing ink or as a colour for decorating surfaces. February 7.

21082. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new colouring matters. January 31.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS.

861. A. Moritz. Improvements in fireproofing felt. January 15.

943. E. B. Manby. See Class XIV.

1089. J. Smith and P. W. Nicolle. Improvements in the treatment of vegetable fibrous matters to obtain fibres therefrom. January 18.

1218. H. H. Boyle. Improvements in machinery for decorticating fibrous grasses and such like substances. January 19.

1267. D. Dregborn and J. Harvey. Improvements in and relating to the treating and scouring of wool, and in the recovery of wool grease, potash, salts, or like products therefrom. January 20.

1364. A. G. Speight. Treating wood-wool to diminish its combustibility. January 22.

1890. J. Marshall, D. H. Thornton, F. H. Cliffe, and W. Cliffe. A new and improved method of and apparatus for preparing and finishing woven fabrics or textile piece goods. January 29.

1948. F. Crosland. An improved composition for rendering, paper, cloth, or other material waterproof. January 30.

2718. E. Meyer. The manufacture or production of a new yarn and of fabrics therefrom. February 7.

2817. H. Robinson. Improvements in apparatus for conditioning yarn. February 9.

#### COMPLETE SPECIFICATION ACCEPTED.

1893.

24,144. E. Samper. A new or improved machine for extracting fibrous matters from agaves, aloes, and other similar plants. February 14.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

1656. J. C. Mewburn.—From La Société Leblois Piceni et Compagnie, France. Improvements in preparing for bleaching and dyeing, and in bleaching, dyeing, and washing vegetable textile material and in apparatus therefor. January 25.

2923. B. Cawthorn and J. P. Cornett. See Class XIX.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

1623. J. Clapham, J. Picard, C. Villedien, and W. W. L. Lishman. Improvements in bleaching and discoloration. January 24.

4067. E. Brook. Improvements in or connected with machines for dyeing, scouring, or drying hanks of yarn or tops. January 24.

6600. A. McMeekin. Improvements in the method of and means employed for bleaching, dyeing, and otherwise treating flax, hemp, and other fibres. February 7.

7350. W. T. Whitehead. Improvements in resists or discharges for use in printing or dyeing cotton, wool, and other fabrics with aniline black. January 31.

7351. W. T. Whitehead. Improvements in resists or discharges for use in printing or dyeing cotton, wool, and other fabrics. January 31.

21,185. L. Weldon. Improvements in dyeing machines. January 24.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

1207. E. T. Hughes.—From H. Howard, United States. Improvements in methods of and apparatus for concentrating sulphuric acid and the like. January 19.

1442. G. S. Johnson. A new compound of sodium sulphite. January 23.

1572. T. Houghton and W. Shield. Improvements in the manufacture of bleaching powder and in apparatus therefor. January 24.

1637. M. N. d'Andria. Improvements in the method of and means for the separation of magnesia from waters and aqueous solutions containing magnesium compounds. January 25.

1905. C. M. Pielsticker. An improved process and apparatus for the production of bichromate and permanganate of potassium. January 29.

2060. H. H. Lake.—From J. B. Tibbits, United States. Improvements relating to the manufacture of lead salts. Complete Specification. January 30.

2373. J. Pedder. Improved process for effecting the desulphurisation of sodic sulphate. February 3.

2486. M. N. d'Andria. Improvements in the recovery of hydrochloric acid and oxide of manganese from solutions of manganese chloride. February 5.

2618. A. Crossley. Improvements in apparatus for producing ferro-ferric and ferric oxides. February 6.

2672. H. R. Angel. Improvements in the manufacture of sulphuric acid. February 7.

2696. A. R. Davis. Improvements in the production of sulphate of manganese and oxide of iron. February 7.

2814. F. E. Matthews. An improved method of storing and utilising chlorine. February 9.

### COMPLETE SPECIFICATIONS ACCEPTED.

18,871. J. Hargreaves and T. <sup>1892.</sup>  
Improvements in the manufacture of alkali and in apparatus therefor. January 21.  
1893.

7107. F. Hurter.—From J. Omholt. Improvements in the manufacture of soda and mono calcic phosphate. February 14.

7108. F. Hurter.—From J. Omholt. Improvements in the manufacture or production of mono calcic phosphate and ammonia. February 14.

1894.

456. P. C. Choate. Improvements in the art of preparing solutions carrying salts of zinc. February 14.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### APPLICATIONS.

878. E. Böhm. Improvements in the manufacture of enamelled glass and crystal glass letters and other devices. January 15.

955. E. F. W. Hirsch. Improvements in glass melting. January 16.

2040. P. B. W. Kershaw and B. Loftus-Tottenham. An improved method of and apparatus for the manufacture of glass balls. January 30.

2689. D. Moore. Improvements in furnaces for annealing glass. February 7.

5505. H. Watkin. Improvements in apparatus for moulding the bodies of electric switches, push-button ceiling roses, and other like articles, in china and earthenware. February 7.

6612. T. W. Twyford. Improvements in the glazing and enamelling of heavy earthenware and other goods, and in apparatus to be employed therefor. February 14.

6661. Craven, Dunnill, and Co., Lim., and F. R. Smith. Improvements in apparatus for the manufacture of tiles. February 7.

### COMPLETE SPECIFICATION ACCEPTED.

1893.

23,388. N. M. Miller. Improvements relating to the rolling of glass, and machinery therefor. January 31.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

1157. H. H. Lake.—From B. Gran, Denmark. Improvements relating to the manufacture of artificial marble. January 18.

1370. A. Hooydonk and H. Hooydonk. A new or improved preparation or compound for decorating the interior of buildings. January 22.

1396. H. H. Leigh.—From G. Bagge, France. Improvements in paving blocks. Complete Specification. January 22.

1427. A. McCara. Improvements in the manufacture of Portland cement. January 23.

1579. H. V. Lanchester. Improvements in the construction of fireproof and like floors. January 24.

2247. D. Belloc and E. Bénard. Improved process for transforming roasted cements into powder, and in apparatus therefor. Complete Specification. February 1.

2322. G. Briggs and M. Leighton. Improvements in the manufacture of paving flags and other articles of concrete. February 2.

2169. F. W. Gallagher and C. M. Jackson. An improved method in the formation and application of building materials, such as clay bricks, wood, stone, concrete, or blocks of other substances. February 5.

2582. C. H. Slier. Improvements in and relating to the production of asphaltic composition in the form of a powder or of a mastic. Complete Specification. February 6.

2678. W. P. Ingham. Improvements in the manufacture of fireclay, bricks, blast-furnace "bumps," and the like. February 7.

2809. H. W. Jeffery. Improvements in or connected with composite road pavements. February 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

1582. F. G. Montagne. Manufacture of artificial marbles. January 31.

3106. W. Webster. Improvements in the manufacture of cement. February 7.

6328. H. B. Allays. An improved process for making mosaics. February 14.

16,454. A. J. Boulton.—From L. P. Hemmer. An improved material adapted for use as a substitute for wood, metal, stone, and other substances. January 31.

17,514. W. Smith. Improved means of protecting timber structures. January 24.

### X.—METALLURGY, MINING, Etc.

#### APPLICATIONS.

998. J. H. Lee. Improved means for separating gold and other metals from other substances by amalgamation. January 16.

1186. J. Pearson and S. Law. Improvements in the method of and means employed in hardening and tempering wire. January 19.

1212. W. S. Squire and L. R. L. Squire. Improvements in the manufacture of metallic zinc. January 19.

1311. J. B. Alzugaray.—From J. E. Torres, France. Improvements in and connected with the reduction, refining, dephosphorisation, and desulphuration of ores, mattes, slags, metals, and alloys. January 20.

1472. A. H. Bell and C. Carter. An improved apparatus for reciprocating gold and silver ores from cyanide solutions. Complete Specification. January 23.

1666. A. Kainer. A new or improved process for heating masses of metal preparatorily to their being further worked. January 25.

1915. W. Klobukowski and M. M. Reicher. New and improved process for producing iron and chromium free aluminium sulphate. January 29.

2041. J. C. Fell.—From the Emmens Zinc Company, United States. Improvements in the treatment of zinc-lead-sulphide ores carrying gold or silver or gold and silver. Complete Specification. January 30.

2236. W. T. Chamberlain. Improvements in explosive metal. February 1.

2361. J. B. Alzugaray.—From J. B. Torres, France. Improvements in and connected with the reduction, refining, and fusing of aluminium, antimony, arsenic, bismuth, cadmium, gold, glucinum, lead, magnesium, silver, tin, zinc, and all other metallic elements from their ores and other compounds. February 3.

2378. G. A. Jarvis. An improvement in the manufacture of steel. February 3.

2527. E. Norton. Improvements in the art or process of manufacturing tin orterne plate. Complete Specification. February 5.

2629. W. P. Thompson.—From J. J. C. Smith and E. C. Smith, United States. Improvements in or appertaining to casting metals. Complete Specification. February 6.

2744. P. R. J. Willis.—From J. H. Hines, United States. An improved process for ornamenting metal. February 7.

2722. J. Lagache. Improved process of treating wavelite and similar minerals. February 7.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

1906. A. V. C. Fenby, J. B. Fenby, and G. Moore. Coating iron and steel with brass and other metallic alloys. January 31.

2119. A. J. Boulton.—From C. G. Richardson and A. B. English. Improvements in or relating to the treatment of metallic ores. February 7.

3583. F. E. de Fursac, J. C. Moisset, and J. P. J. Very. Processes of separating metals, covering scraps, clippings, or other pieces of metal of all kinds. January 23.

5568. T. Twynam. Improvements in the manufacture of steel and ingot iron. January 24.

7252. W. Hayward. A new or improved process for recovering zinc or spelter from waste galvanised iron and steel, and furnaces and appliances for the said process. February 7.

23,425. W. P. B. Urick. Improvements in methods of casting solid ingots of steel. February 14.

23,979. F. W. Golby.—From C. Francisci. Improvements in furnaces for distilling zinc, cadmium, and the like. January 31.

### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

#### APPLICATIONS.

1356. E. Andreoli. Improvements in electrolysis. January 22.

1440. J. Peel. Improved electric battery. January 23.

1744. W. S. Rawson. Improvements in electro-deposition. January 26.

1903. M. Wuillot. Improvements in or relating to electrodes. January 29.

2250. O. Hund.—From G. Wehr, Germany. Improvements in galvanic batteries. February 1.

2251. O. Hund.—From G. Wehr, Germany. Improvements in galvanic dry batteries. February 1.

2487. C. J. Hall. Improvements in or relating to secondary batteries. February 5.

2806. C. Kellner. Improvements in electrolytical decomposing apparatus. February 8.

2897. C. P. Shrewsbury, F. L. Marshall, J. Cooper, and J. L. Dobell. Improvements in the manufacture of coke or carbon for electrical or other purposes. February 9.

2900. J. Rudholzner. Improvements relating to the electro-deposition of metals. Complete Specification. February 9.

2968. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brüning, Germany. An improvement in electrolysing liquids and apparatus therefor. February 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

2267. C. T. J. Vantin. Improvements in the method of and apparatus for the electrolytical separation of the bases of salts, and of compounds of the same, from saline solutions. January 31.

3477. H. Nehmer. Improvements in constructing and connecting galvanic elements. February 14.

3573. E. Taussig. Improvements relating to the extraction of metals by means of electricity and to apparatus therefor. February 14.

5778. A. J. Boulton.—From O. Knoefler and F. Gebauer. An improved process for manufacturing bleaching solutions by electrolysis. January 24.

5844. W. P. Thompson.—From M. Hartung. Improvements in storage batteries. January 31.

19,967. W. Petschel. Improvements in secondary electric batteries. February 7.

22,956. C. A. J. H. Schroeder and H. E. R. Schroeder. New improved electro-positive galvanic battery electrodes. January 31.

23,913. R. Hadden.—From H. S. Blackmore. Improved process and apparatus for dissociating soluble salts by electrolysis. January 24.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

963. F. Burton. A process for the purification of oils, fats, and the like. January 16.

1088. A. Warwick, J. Smith, and P. W. Nicolle. Improvements in the manufacture of soap and washing compounds. January 18.

1237. M. H. Tomkins and F. Woodman. An improved cleansing compound for cleaning wood, stone, and other surfaces. January 19.

1296. F. R. Donisthorpe. Improvements in or relating to the manufacture of soap. January 20.

1758. J. C. W. Stanley. Improvements in or relating to the recovery of oil from fish, fish offal, and the like. January 26.

1760. T. F. Alten. Improvements in or relating to soap. January 26.

1764. J. C. W. Stanley. Improvements in or relating to the extraction of oil or grease from other materials. January 26.

1963. A. R. Scott. Improvements in the manufacture of cleansing or soap powder for washing fibrous and other materials. January 30.

2132. E. Petit. Improvements in the acid saponification of fatty bodies and in apparatus employed therein. January 31.

2701. T. de Zebrowski. Manufacture of a new or improved soap. February 7.

2871. C. Heydemann.—From O. Dennerlein, Holland. An apparatus for melting and purifying fats. February 9.

2896. N. Iseli. Improvements in or relating to the manufacture of alcohols, oils, greases, and other matter. February 14.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

5040. The Patent Syndicate Lightning Oil Extractor Co., Ltd., and H. A. A. Dombrain. Apparatus for driving off heavy vapours of solvents. January 24.

5621. J. Peacock and W. L. Colls. Improved manufacture or production of soap. January 24.

6123. W. Brothers. Improved detergent compound or preparation for the washing or scouring of textile fabrics or other articles. February 7.

6993. R. Hutcheson. Improvements in treating wool greases and separating their constituents. February 7.

9105. C. D. Abel.—From the Fabriques de Produits Chimiques de Thann et de Mulhouse. An improved manufacture of oils, fats, wax, and other analogous substances freed from odour and flavour. February 14.

24,461. T. Cordweener and A. de Kunwald. See Class XVIII. (A.)

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

### APPLICATIONS.

958. J. Hickisson. Improvements in marking-ink pencils. January 16.

1107. D. Forbes and C. Hoddell. Enameline. January 18.

1301. J. W. Blake and S. J. Blake. Improvements in compositions or paints for preserving ships' bottoms and other structures. Complete Specification. January 20.

1418. J. P. Lacy and A. J. Ash. Improvements in the production of zinc compounds, suitable for use as pigments and for other purposes. January 23.

2257. I. F. Clark. A substitute for veneer or enamel. February 2.

2428. D. J. Harris. A composition or solution for making waterproof, hardening, and preserving the soles of boots and shoes. February 3.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

7117. A. C. J. Charlier. Improvements in apparatus for the manufacture of metallic pigments or compounds, and in the production of lead pigments or compounds by means of such apparatus. February 14.

7571. C. D. Abel. From the Westfälisch-Anhaltischen Sprengstoff Actien Gesellschaft. Hygroscopic paint or coating material for keeping packing cases dry. February 7.

10,619. W. Ward and J. O. Wallace. A new or improved paint. February 14.

22,137. L. Paget. Improvements in pyroxyline compounds, solutions, and solvents. January 31.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### APPLICATIONS.

943. E. B. Manby. An improved sizing, dressing, and finishing material for application to textile fibres and fabrics. January 16.

977. G. W. Ewens. A new material for use as a substitute for leather for floor coverings and for like purposes. January 16.

2079. G. E. Wiese. Improvements in the manufacture of liquid glue. Complete Specification. January 31.

2175. J. Grillo and M. Schroeder. Process for the production of glue and gelatin from bones. Complete Specification. February 1.

2517. W. H. Jeansson. Improvements in the treatment of leather. February 5.

2978. A. J. E. Hill and F. P. Hill. Improved waterproof glue. February 10.

## XV.—AGRICULTURE AND MANURES.

### APPLICATION.

2624. J. J. Seldner and J. Watson, jun. Improvement in the manufacture of fertilisers. Complete Specification. February 6.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

### APPLICATIONS.

1146. C. H. Meyer. Improvements in the manufacture from starch or starchy substances of a material suitable for use in brewing and for other purposes. January 18.

1790. D. Stewart. Improvements in centrifugal apparatus for drying and purifying sugar or other crystalline or granular matters. January 27.

1953. E. Shaw. Improved apparatus for boiling sugar and glucose, either separately or mixed. January 30.

2732. E. Shaw. Improved apparatus appertaining to the process of boiling sugar and glucose, either separately or mixed. February 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

7695. L. E. A. Prangey. Improvements in the continuous refining or bleaching of sugar, and in machines employed for this purpose. January 24.

1894.

136. H. H. Lake.—From P. H. V. Weyde and O. Lugo. Improvements in the manufacture of sugar. February 7.

### XVII.—BREWING, WINES, SPIRITS, ETC.

#### APPLICATIONS.

1146. C. H. Meyer. See Class XVI.

1153. F. D. Fisher. Improvements in brewing. January 18.

1717. R. R. P. Schmiedeecke and E. O. Gade. Improvements in apparatus for the preparation of malt. Complete Specification. January 26.

2889. G. G. Cave. Improvements in the treatment of yeast. February 9.

2922. W. S. Squire. Improvements in the treatment of distillers' spent wash. February 10.

2966. W. R. Reffell. An external mashing apparatus for the use of brewers and others in mashing malt with water or raw grain liquor in brewing or distilling. February 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

1887. F. M. Polsky. Improvements in the manufacture of yeast. January 24.

4981. F. E. V. Baines. Improvements in the treatment of rice or other grain for the production therefrom of a material suitable for use in brewing or for other purposes. January 24.

5870. H. H. Lake.—From K. Müller. Improvements relating to the clarification of beer. January 31.

23,367. L. Wagner and J. Marr. Improvements in the methods of extracting liquids from and drying grain, malt, brewers' grains, and other like substances, and in apparatus therefor. February 14.

### XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

#### APPLICATIONS.

##### A.—Chemistry of Foods.

1170. R. F. Maclosky.—From J. H. Niemann, Australia. A new or improved meat extract. Complete Specification. January 19.

1405. F. T. Bond. Improvements in the preparation of cheese. January 23.

1564. J. F. Duke. Improvements in the method of preserving eggs. January 24.

2129. W. P. Thompson.—From G. B. R. von Poschinger, Germany. An improved process and apparatus for preparing or producing a fodder material. January 31.

2445. C. Kidson. A new method of preserving eggs. February 5.

2651. T. Charlton and A. H. Cannon. Improvements in and connected with the preservation, storage, and revivification of alimentary substances. February 7.

##### B.—Sanitary Chemistry.

1086. E. C. Ives and J. Woodlatt. An improved filter for use in purifying polluted waters, sewage, and the like. January 18.

1591. W. D. Scott-Monerieff. Improvements in apparatus for the treatment of sewage. January 24.

1762. C. Salzberger. Improvements in or relating to the disinfection or purification of water. January 26.

1865. E. C. Ives. An improved system of purifying sewage or other foul waters. January 29.

##### C.—Disinfectants.

1415. I. Levinstein. Improvements in and connected with iron compounds for use in precipitating sewage, purifying waste liquors, colouring, and the like purposes. January 23.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### A.—Chemistry of Foods.

1893.

6596. E. Sonstadt. Improvements in the preparation of extracts of tea and coffee, and in utilising a by-product of the process. February 7.

10,689. M. Watson. An improved preparation of malted pulse food. January 31.

24,191. B. Haddan.—From La Compagnie du Sel Agglomere. Improvements in and relating to the treatment of salt and the formation of blocks thereof by fusion. February 14.

24,461. T. Cordewener and A. de Kunwald. Improvements in and in apparatus for the manufacture of margarine and alimentary fat. January 24.

##### B.—Sanitary Chemistry.

23,082. S. Smithson. Improvements in or relating to machinery or apparatus for treating, deodorising, drying, and utilising excreta, nightsoil, towns' refuse, and the like. February 7.

##### C.—Disinfectants.

4950. C. R. Alder Wright. Improvements in the manufacture of antiseptic and disinfectant materials for sanitary purposes. January 31.

7038. S. Pitt.—From The Chemische Fabrik auf Actien vormals E. Sehering. A new antiseptic material to be called "Formalin." February 14.

12,276. E. Soy. Improvements in vessels for containing liquefied sulphur dioxide for use as a disinfectant and vermin destroyer, and for other medical and sanitary purposes. January 31.

### XIX.—PAPER, PASTEBOARD, ETC.

#### APPLICATIONS.

1067. H. H. Lake.—From La Société J. Noé et P. Putois, France. Improvements relating to the manufacture of artificial whalebone. January 17.

1345. J. Lander. A process for expanding celluloid and celluloid tubes into any required shape. January 22.

1599. H. G. Cadywould. Damp-resisting paper. January 25.

2214. J. La-Bua. A machine for coating photographic paper tracing paper and coloured paper with one colour only. February 1.

2923. B. Cawthorn and J. P. Cornett. Improvements in or connected with the process of bleaching fibrous materials in the manufacture of paper. February 10.

#### COMPLETE SPECIFICATION ACCEPTED.

1893.

24,652. W. M. C. Callender. The manufacture of a new material designed to serve as a substitute for bone or celluloid. February 7.

### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

#### APPLICATION.

1287. F. W. Warriek. An improved pharmaceutical preparation of ferrous salts. January 20.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

2951. J. Morris. Means for using certain chemicals, drugs, and perfumes for therapeutic, disinfecting, antiseptic, and perfuming purposes. February 14.

6596. E. Sonstadt. *See* Class XVIII. (A.)

6749. C. Kolbe. Manufacture or production of salols. February 7.

22,931. F. W. Warriek. An improved pharmaceutical preparation of ferrous salts. January 31.

### XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

#### APPLICATIONS.

1109. T. Maloni. Improvements in and connected with lighting apparatus for taking photographs at night or in dull weather. January 18.

2036. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Scherl, Germany. Improvements in the treatment of gelatinous matter and the production of photographic films. January 30.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4214. W. H. Walker. New or improved apparatus for the manufacture of films, more especially intended for the manufacture of films for photographic purposes. January 31.

5517. W. H. Prestwich. Improved silver haloid emulsions for photographic purposes. February 14.

5932. O. Magerstedt. An improvement in the manufacture of photographic plates. January 24.

6491. E. Norden. An improved method of photographic printing in bromide of silver. January 31.

6501. C. A. Allison.—From F. B. Forster and G. G. Rockwood. Improvements in processes of making transparent photographs on glass. February 14.

### XXII.—EXPLOSIVES, MATCHES, Etc.

#### APPLICATIONS.

1074. M. von Förster. Improvements in or relating to the manufacture of smokeless powder. January 17.

1665. E. Rubin. Improvements in percussion fuses. January 25.

1722. R. H. Panshon. An improved explosive compound. January 26.

1755. F. J. Smith. Improvements in detonators. January 26.

1846. G. E. Cassel and D. Kempe. An improved process of preparing pine or analogous wood for the manufacture of matches. Complete Specification. January 27.

1982. V. I. Feeny.—From The United States Smokeless Powder Co., United States. Smokeless powder. Complete Specification. January 30.

2144. F. J. Maubeuge. Improvements in combined time and percussion fuses. January 31.

6775. I. M. Meissner. An improved igniting composition for matches. February 14.

#### COMPLETE SPECIFICATION ACCEPTED.

1893.

8677. J. V. Landuyt. Improvements in apparatus for use in the manufacture of matches and for putting the same in boxes. February 7.

# THE JOURNAL OF THE Society of Chemical Industry: A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 3.—Vol. X. (1.)

MARCH 31, 1894.

Non-Members 50/- per annum; Members  
2/- per Set of extra or back numbers;  
Single Copies (Members only) 2/6.

## The Society of Chemical Industry.

### Past Presidents:

Mr. H. E. Kewen, M.D., F.R.S.	1881—1882.
Mr. Frederick Abel, Esq., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.

## NOTICES.

Notice is hereby given in accordance with Rule 54 of the By-Laws that the Council will propose to the forthcoming Annual Meeting the amendment of the Society's By-Laws as follows:—

1. That *Rule 7* be amended by the deletion of "and" in the first line thereof, and by the addition of the words "and 47" in the same line.

2. That under *Rule 18* the form of nomination of candidates for the Council be amended by transferring the candidate's declaration to the end thereof, and that the words "and by the nominee" be added in the third line after the above-mentioned form after the word "subscriptions."

3. That the proviso at the end of *Rule 22* be deleted.

4. That in *Rule 26* the Nomination Form for candidates for Membership be amended to read as follows:—

"We, the undersigned members of the Society of Chemical Industry, hereby propose  
(*candidate's name in full*) as a fit and proper person to become a member of the Society.

*For names only of members }  
recommending the candidate. }*

"And I, the said candidate for membership, hereby declare that if elected I will do my best to support the Society and will observe its By-Laws.

(Signature) \_\_\_\_\_ (Profession) \_\_\_\_\_

(Address) \_\_\_\_\_ (Date) \_\_\_\_\_

*Extract from By-Laws (Rules 27, 29, and 30).*

5. That *Rule 27* should read as follows:—

"Each member shall pay an annual subscription of twenty-five shillings, due on the 1st January in each year; except that any member may pay a life composition fee of twenty pounds in lieu of an annual subscription. He shall also pay on receipt of notice of election an entrance fee of one guinea in addition to his first year's subscription; except that should a member who has paid an entrance fee resign and subsequently seek re-election the Council may dispense with a further entrance fee."

6. That in the second line of *Rule 28* the words after "and" read as follows:—"issued to the members once every year."

7. That *Rule 29* read as follows:—

"No person shall be entitled to the privileges of membership who has not paid his subscription for the current year. He shall not attend meetings nor vote, nor shall he receive gratuitously the publications of the Society. Should the subscription remain unpaid eight months after it is due, the Secretary shall give the member notice that unless payment be made within four months after the date of such notice, his name will be struck off the register. At the expiry of the said period, if the member should still remain in default, the Council may order his name to be removed from the register, whereupon he shall cease to have any right, privilege, or interest in the Society, and the Council may notify the same in the Journal and recover the arrears of subscription at law."

8. That *Rule 30* read as follows:—

"Any member may withdraw from the Society at the end of any year by giving previous notice to the General Secretary of his intention to withdraw; always provided that such notice to be valid must be accompanied by the payment of all subscriptions, if any, which may be due from him to the Society at the date of the notice. By such notice and payment he shall be released from all further liability as a member."

9. That the following Rule be added after *Rule 53* of the present Rules:—

"All communications between Local Sections and Public Bodies or Societies shall be conducted through or be at the discretion of the Council; and no publication shall be issued by any Section to the general public without the previous consent of the Council."

10. That *Rules 54* and *55* be placed after *Rules 34* and *38* respectively, and that the succeeding Rules be renumbered accordingly."

#### BANKERS' ORDERS.

For the convenience of Members, the Treasurer has arranged with the Bankers of the Society that they shall collect subscriptions from Bankers in town and country; and Members, who have not already done so, are invited to fill up and sign the Banker's Order enclosed with the December number of the Journal, which should then be sent to the Honorary Treasurer, Mr. E. Rider Cook, East London Soap Works, Bow, E.

#### ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Edinburgh on the 18th, 19th, and 20th July next. Full particulars will appear in a subsequent issue.

#### INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

We are requested by the Foreign Office to state that an International Congress, under the patronage of the Belgian Government, will open in Brussels on the 4th August next, in connection with the Antwerp Exhibition, on the subject of applied Chemistry.

The work of the Congress will be divided into four sections corresponding to those of the Belgian Chemists' Association, viz.:—Sugar, Agricultural Chemistry, Food-stuffs, and Biological Chemistry.

Those who desire to attend the Congress should apply to M. Sachs, 68, Rue d'Allemagne, Brussels (Sugar and Agricultural Chemistry), or to M. H. van Laer, 15, Rue de Hollande, Brussels (Adulteration of Food-stuffs, and Biological Chemistry), who will forward full particulars on application.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

#### LIST OF MEMBERS ELECTED 21st MARCH 1894.

Bailey, Wm., Graedien, Alloa, N.B., earthenware manufacturer.

Barratt, W. S., 40, Heywood Street, Moss Side, Manchester, science teacher.

Beaman, H. S., 18, Mavilla Gardens, North Kensington, W., brewer and analytical chemist.

Bowman, Jas. H., Canada Chemical Manufacturing Co., London, Ont., Canada, professor of chemistry.

Bryce, Thos., Tharsis Mines, Huelva, Spain, chemist.

Cox, Robt., 34, Drumsheugh Gardens, Edinburgh, gelatine manufacturer.

Darling, Geo. A., c/o Robinson G.M. Co., P.O. Box 1024, Johannesburg, S.A.F., metallurgist.

Fairweather, Wallace, 62, St. Vincent Street, Glasgow, chartered patent agent.

Friedman, Chas. S., 1616, Montgomery Avenue, Philadelphia, Pa., U.S.A., chemist.

Fuerst, Dr. Alex. F., 30, Belsize Road, London, N.W., chemist.

Goodwin, Prof. Wm. L., The School of Mining, Kingston, Canada, professor of chemistry.

Goskirk, Alex., 28, Hillside Street, Edinburgh, electric metallurgist.

Græff, Robt. W., 29, Miacing Lane, London, E.C., chemical agent and merchant.

Heap, Isaac H., Fern Bank, Aynsley Road, Stoke-on-Trent, pharmaceutical chemist.

Henderson, Jos., 13, Denmark Street, Darlington, analyst.

Hopkins, Herb. W., 13, Harrington Gardens, South Kensington, S.W., metallurgist.

Jarvis, Talbot McL., Castle Lodge, Bedford, brewer.

Langrick, Thos. E., 3, Cambridge Avenue, Edinburgh, paint works manager.

Llewellyn, Geo. H., Pencreaig, Caerau Park, Newport, Mon., science student.

McAlley, Robt., 43, King William Street, Greenwich, S.E., paint works manager.

McDonald, John, Distillery Offices, Fort William, N.B., distiller.

McVitie, Robt., 8, Torphichen Street, Edinburgh, biscuit manufacturer.

Moffat, Alex., c/o Linlithgow Oil Company, Limited, Linlithgow, N.B., analytical chemist.

Muspratt, Max., Scaforth Hall, Scaforth, Liverpool, technical chemist.

Oliver, Jas. M., Kirkealdy, N.B., engineer.

Pearson, Wm. H., Bryn Villas, Blaina, Mon., analytical chemist.

Rose, Andrew A., 172, Leith Walk, Edinburgh, merchant.

Rose, Hugh, 172, Leith Walk, Edinburgh, paint and varnish manufacturer.

Shalleross, Arthur, 19, City Road, Openshaw, Manchester, chemical manufacturer.

Shupley, Fred., c/o W. P. Fuller and Co., 21, Front Street, San Francisco, Cal., U.S.A., paint works chemist.

Smith, J. Cruickshank, 32, Great Guildford Street, Southwark, S.E., assistant chemical manager.

Watson, A. Forbes, 11, York Place, Edinburgh, assistant in chemical department, Edinburgh University.

Watson, Chas. S., 9, Princes Street, Pollokshields, Glasgow, analytical chemist.

#### CHANGES OF ADDRESS.

Auerbach, Dr. C. G., 1/o Ludwigshafen; 1. 7.4., Mannheim, Germany.

Barracough, W. H., 1/o Forest Gate; 83, Bedford Road, Ilford, Essex.

Bernard, Jas., 1/o Braço de Prata; Casal das Rollas, Olivaes, Lisbon.

Beveridge, Jas., 1/o Northfleet; Sulphite Pulp Mills, Hjerpen, Sweden.

Bowman, Dr. F. H., 1/o Halifax; Ashleigh, Ashley Heath, Bowdon, Cheshire.

Douglas, Wm., 1/o Demerara; 35, Vartry Road, Stamford Hill, N.

Fanta, F., 1/o Gresham Street; Effingham House, Arundel Street, Strand, W.C.

Frew, Dr. Wm.; Journals to Ottostrasse 13<sup>m</sup>, München, Bavaria.

Fryer, Dr. A. C.; 1/o Cornwallis Lodge; 13, Eaton Crescent, Clifton, Bristol.

Gamble, D., jun., 1/o Prescot; Bryn Eithyn, Colwyn Bay, North Wales.

Gibbins, H. B., 1/o Bath; Inglescombe, Manor Park, Redland, Bristol.

Haller, G., 1/o 86A; Sussex House, 52, Leadenhall Street, E.C.

Harrison, C., 1/o Sheffield; Hayle, Cornwall.

Hartley, Jns., 1/o Manchester; Ballavartyn, Santon, near Douglas, Isle of Man.

Jarmain, G. S., 1/o Marsh; Minerva Works, Turnbridge, Huddersfield.

Jarvis, Talbot; Journals to 51, Pembury Road, Tonbridge, Kent.

Lange, Dr. M., 1/o Amersfoort; Westerdokstraat 25, Amsterdam, Holland.

Lindley, H. L., 1/o Camden Road; Chemical Laboratory, Royal Veterinary College, Camden Town, N.W.

Love, Dr. E. G., 1/o 54th Street; 80, East 55th Street, New York, U.S.A.

Maenair, Dr. D. S., 1/o London; 2, Grosvenor Terrace, Hillhead, Glasgow.

McVitie, Robt.; Journals to Derwent Mills, Malton, Yorks.

Morris, Dr. G. Harris; Journals to 18, Gwendwr Road, West Kensington, W.

Newton, H. C., 1/o Bronesbury; 8, Hldgrave Road, South Hampstead, N.W.

Pearce, Wm., 1/o Brentwood; The Lhus, Salway Hill, Woodford, Essex.

Pettigrew, R., 1/o Andrie; c/o Mersey and Irwell Joint Committee, 41, Mosley Street, Manchester.

Rhodes, Jos., 1/o Glasgow; Old Park Printing Works, Belfast.

Roberts, Ernest H., 1/o Wandsworth; Chemical Works, Wicklow, Ireland.

Seymoure, A., 1/o Box 1283; Box 20, Johannesburg, S.A.R.

Saltmarsh, J. G., 1/o Brooks Bar; 103, Park Street, Greenheys, Manchester.

Sandon, R., 1/o Tufnell Park; 42, Lewisham Road, Dartmouth Park, N.W.

Savin, Chas., 1/o Laurence Pountney Hill; c/o Dollman and Pritchard, 39, King Street, Cheapside, E.C.

Sharp, H., 1/o Brookenhurst; 11, Delahay Street, Westminster, S.W.

Sisson, G., 1/o Manchester; c/o Washington Chemical Co., Lim., Washington Station, R.S.O., co. Durham.

Sowler, Alf., 1/o Beckenham; 208, Bedford Hill, Balham, S.W.

Turner, Thos., 1/o Birmingham; County Offices, Stafford.

Tweddie, G. R., 1/o Margate; Puckstone, near Sturry, Kent.

Wade, W. L.; Journals to 62, Nine Elms Lane, S.W.

White, W. H., 1/o Killingworth House; The Cottage, Killingworth, Newcastle-on-Tyne.

Wilder, F. L.; Journals to St. John Del Rey Mining Co., Morro Velho, c/o P. S. Nicolson and Co., Rio de Janeiro, Brazil.

Wingham, A., 1/o London; 3, Lincombe Views, Warren Road, Torquay.

Wood, Jos. T., 1/o Hound Road; 29, Masters Road, West Bridgeford, Nottingham.

Wright, L. T., 1/o Buenos Ayres; 10, Hazlitt Road, Sinclair Road, London, W.

#### RESIGNATIONS CANCELLED.

Davis, H. W., Government Laboratory, Somerset House, W.C.

Schlichter, Dr. H., Thothmes House, Gisburn Road, Hornsey, N.

#### CHANGE OF ADDRESS REQUIRED.

Houmfray, D.; 1/o 42, South Street, Greenwich, S.E.

#### ERRATA IN LIST.

Jürgensen, Dr. Rolof (wrongly spelt "Türgensen"). Prague, Austria.

Stone, Frank (Christian name wrongly given as "William"), Melbourne, Victoria.

#### Drath.

Bicket, J. Hugh; 1/o The Limes, Stamford Hill, N.

## London Section.

THE CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE, W.

Chairman: Wm. Thorp.

Vice-Chairman: W. Crowder.

### Committee:

E. J. Bevan.  
W. G. Blagden.  
C. C. Hutchinson.  
T. A. Lawson.  
R. Messel.  
B. E. R. Newlands.  
W. Ramsay.

F. G. Adair Roberts.  
A. Gordon Salamon.  
G. N. Stoker.  
F. Napier Sutton.  
T. Tyrer.  
Frank Wilson.  
C. R. Alder Wright.

Hon. Local Secretary: John Heron,  
74, North Side, Clapham Common, S.W.

### SESSION 1893-94.

#### REMAINING MEETINGS.

First Monday in each Month at 8 p.m.

- April 2nd:—  
Mr. J. W. Lovibond. "Colour as a means of Quantitative Estimation."  
Mr. W. C. Young, F.I.C., F.C.S. "The Natural Diminution of the Dissolved Organic Matter in the Water of Rivers."  
Mr. H. Louis, A.R.S.M., F.I.C., F.C.S. "Note on an Improved Specific Gravity Bottle."
- April 16th:—  
Mr. H. de Moersenthal, F.I.C., F.C.S. "On the Treatment of Gold Ore at the Witwatersrand Gold Fields."
- May 7th:—  
Mr. Claude Vautin. "The Commercial Analysis of Fused Salts."  
Messrs. W. H. Stanger, M.I.C.E., F.C.S., and B. Blount, F.I.C., F.C.S. "The Testing of Hydraulic Cements."  
Mr. W. Gowland, A.R.S.M., F.I.C., F.C.S. "A By-product obtained in Liqutating Copper with Lead."
- May 21st:—  
Mr. F. Platten. "A Modification of the Ferric Chloride Distillation Process for Estimation of Arsenic in Copper."  
Mr. Oscar Guttman, M.I.C.E. "The Manufacture of Smokeless Powder."
- June 11th:—  
Mr. W. G. McMillan:  
(a.) "Experiments on the Strength of Leather."  
(b.) "Note on the Colour of Brass."  
Mr. P. Dvorkevitch. "Distillation of Peat."

Notices of the Meetings appear regularly in the Scientific Press.

Meeting held Monday, February 5th, 1894.

#### NOTE ON AN INTERESTING EXPLOSION CAUSED BY SODIUM PEROXIDE.

BY A. DUPRÉ, PH.D., F.R.S.,

Chemical Adviser to the Explosives Department of the Home Office.

On the evening of March the 9th, 1893, an explosion happened in the goods station of the Midland Railway in Whitecross Street, and on the following morning the scene was visited by Colonel Majendie, C.B., and myself. We found numerous signs that an explosion of some violence had taken place. The box which had contained the material causing the explosion had disappeared, but fragments of it were scattered about the station, some striking the roof and others the skylights, breaking some of the panes of glass. Eight tins which, it was said, were in the box, had either disappeared entirely or were scattered in fragments all over the station. Near to the scene of the explosion, the platform, the pillars supporting the roof, other ironwork, and the roof itself, were splashed over with a white substance, evidently projected by the explosion. The van on which the box had been, and the platform

against which the van stood, had suffered a little from fire, but no structural damage had been done to any part of the building.

On investigation it was found that the box which exploded had contained sodium peroxide, packed in 14-lb. tins, eight of which were said to have been in the box. Besides this box there were on the van a larger box also containing peroxide (this on subsequent examination was found to contain 19 14-lb. tins of peroxide and one empty tin), five casks of a concentrated solution of sodium bisulphite, two casks of sanitas, a box of colour, and a parcel of drapery. The van, which arrived at the station at 8 p.m., had been backed against the platform, and everything, except three casks of bisulphite solution and the box which subsequently exploded, had been removed from the van by 9.15 p.m. At 9.50 two porters, Hill and Rose, returned to the van to complete the unloading. Hill first proceeded to remove the box, which, since it was first put into the van, had rested undisturbed on the top of two of the casks of bisulphite. He had lifted the box down on to his knees, and was either letting it down to the floor of the van, or was turning it over to place on the platform, when he heard a hissing noise coming from the box, and Rose, on turning round, saw flames issuing from it. Rose at once ran away towards the gates of the station, and while so engaged (about four or five seconds), having fallen off the platform in his hurry, four loud explosions followed each other in rapid succession, filling the station with a black smoke and setting fire to the tarpaulin of the van. Hill, who had remained on the van till after the first explosion, jumped down and also ran away; he was not seriously injured. The police and firemen from stations near, having been alarmed by the noise of the explosions, speedily arrived and put out the fire.

Inquiry showed, beyond all reasonable doubt, that the box which exploded had contained peroxide of sodium packed in square 14-lb. tins. The next step, therefore, was to ascertain how this material could have caused the explosion. For this purpose numerous experiments were made by Mr. Archbutt and myself, which fully satisfied us that sodium peroxide by itself could not be exploded either by compression, friction, or heat, even that of an oxyhydrogen blowpipe. Even the explosion of a 30-grain detonator inserted into the middle of 1 lb. of peroxide packed in a double, strong tin canister, failed to induce any decomposition. These experimental results are corroborated by theoretical consideration. The formation of sodium peroxide is not an endothermic reaction, and hence the peroxide is not one of those compounds liable to spontaneous decomposition. I have been unable to find any record of the heat value of this reaction, and some experiments which I hoped to lay before you have not yielded numerical results sufficiently accurate to warrant their publication. Nevertheless the experiments clearly show that a considerable amount of heat is evolved during the conversion of  $\text{Na}_2\text{O}$  into  $\text{Na}_2\text{O}_2$ .

When water is added to sodium peroxide much heat is liberated, some peroxide of hydrogen is formed, and oxygen and steam are evolved. The decomposition, however, has no tendency to spread, but is always strictly confined to the portion wetted. Numerous experiments were made on this point, and always with the like result.

When, however, the peroxide is mixed with, or is even in contact only with, any combustible, the result is very different. In this case the combustible matter in contact with the peroxide readily takes fire when the latter is moistened, and if anything like an intimate mixture of the two has taken place a more or less violent explosion is the result. The mixtures of the peroxide with wood meal, wood shavings, hay, cotton, wool, sulphur, and even bisulphite of sodium, readily take fire or explode when simply moistened with water. Experiments illustrating the facts were shown. A slightly rough deal board can be set on fire by merely covering it with a layer of peroxide and dropping water on it. When once the combustible has taken fire a very fierce combustion results as long as any peroxide is left, the effect being greatly enhanced by the melting of the peroxide, which wherever it flows sets fire to everything combustible. Sodium peroxide, as is of course well known, is a very powerful oxidising agent, but it differs from most

other agents of the kind by the fact that its power can be called forth both by fire and by water, and it is this latter fact chiefly which renders it so dangerous. In this behaviour we have, in my opinion, an explanation of the explosion under consideration. A qualitative analysis of various portions of the white substance splashed about, as before stated, in the neighbourhood of the explosion, revealed the presence of much sulphite and sulphate of sodium, besides the presence of caustic soda, carbonate of sodium, ferrate of sodium, globules of melted iron and tin, and in some cases of a sulphide. A quantitative analysis of some of the material projected against the roof, made by Mr. Archbutt, gave the following result:—

Sodium carbonate.....	9.55
Sodium sulphate.....	6.41
Sodium sulphite.....	52.98
Black insoluble matter, much organic matter with oxide of iron and particles of metallic iron or tin.....	31.06
	<hr/> 100.00

This material had undoubtedly come from the exploded box (the casks of bisulphite solution were found full and uninjured after the explosion), and gives, I think, the key to the solution of the difficulty. There can, I believe, be little or no doubt that besides the peroxide the box contained some sulphur compound, perhaps in the form of a strong solution. By the tilting of the box this solution came into contact with some of the peroxide which during transport had escaped from one or more of the by no means very strong tins and thus led to the accident. I am fully aware that many objections may be raised against this explanation, and shall be very glad to hear any remarks from members of this Society, many of whom must be familiar with this material. The lesson to be learnt from this explosion, whether the attempted explanation be accepted or not, is, however, clear. Peroxide of sodium should always be packed in strong metallic cases not liable to injury during ordinary transport, and should be carefully kept apart from all kinds of combustible matter.

I cannot conclude without expressing my thanks to Mr. Archbutt for the valuable help he has afforded me in the investigation of the cause of this explosion.

#### DISCUSSION.

Mr. TYLER, whilst paying a tribute to the careful work of Dr. Dupré, said that to his mind no satisfactory cause had been given. He had had considerable experience with sodium peroxide, from its earliest production, when it was much less pure, to the present article supplied by the Aluminium Company, which was very pure. One point had been overlooked, and that was the presence of small pieces of metallic sodium, which occasionally occurred in less pure specimens. There had been no evidence of leakage from the tins or from any other package into the tins, so he could not consider the explanation satisfactory. He had also tried all the experiments which Dr. Dupré had made that evening, and although plenty of heat and sometimes light were produced by the mixture of sodium peroxide with other substances and water, he never had had a violent explosion. He would add that his experiments were made, not on small, but on considerable quantities of materials, thus resembling the conditions given. It was only fair to the important industry connected with peroxide production to emphatically state that sodium peroxide *per se* was absolutely harmless, and, as far as his experience went, a most difficult compound with which to produce a violent explosion.

Mr. D. HOWARD said it was a great many years since gunpowder was invented, and it was discovered that three harmless substances properly mixed up had very unpleasant properties. Unfortunately the lesson which was thus taught was not sufficiently appreciated, viz., that perfectly harmless things if mixed together had very unpleasant results. He wished that those who had charge of the carriage of goods would learn the lesson. The popular idea was to put all

dangerous things together. In his boyhood there was a very ugly fire at one of the docks, said to have arisen from the impression that jute, cubic nitre, and sulphur were dangerous things, and, therefore, should be stored in the same warehouse. The story went that the jute and sulphur were on the lower floor, and the nitre on the top, and the heat causing the nitre to melt they could imagine what happened. This might not have been an absolutely true account, but it illustrated the sort of feeling people had that all dangerous things should be put together, then which there could not be a more dangerous delusion. He feared there was an idea that peroxide of sodium was one of these horribly dangerous things which were to be put with other dangerous articles, and, therefore, it seemed to him there was great value in Dr. Dupré's careful experiments. Peroxide of sodium was apparently absolutely incapable of explosion unless mixed with something else with the very something else with which it was likely to be brought in contact on the principle he had enunciated. It was very clear that what was required was an absolutely careful package. He did not know what the package might have been in this case, but he had known nitric acid of 1.500 specific gravity packed in sawdust, and the result was not unlike Dr. Dupré's description, but happily it took place in an open yard. This was sent to him to be shipped under deck. Peroxide of sodium should be packed with mineral meal, or something of that kind perfectly incombustible, and under those circumstances it would be perfectly safe. On the other hand, if it were badly packed to begin with, and then put in dangerous company, no doubt it might become a source of serious danger. The idea that because a thing could explode it was to be condemned was a very serious evil. There were very few things which would not explode. It had been recently discovered that methylated spirit on being shaken up and held to a candle gave a considerable rush of flame, but he had known that about as long as methylated spirit had been made. In fact there was hardly anything which could be burnt which would not make an explosion if you went the right way about it. But, on the other hand, there was hardly anything, even of a decidedly dangerous character, which might not be safely dealt with and transported if proper precautions were taken.

Dr. SQUIRE said that if a tin in which there was a crack were plunged into a solution of bisulphite of sodium, that crack would develop into a hole, and then all the rest might follow.

The CHAIRMAN said that Mr. Howard had given very good advice as to the danger of relegating all so-called dangerous substances to the same class, but he feared that advice would not reach the right people, but that the railway companies would continue to put all kinds of things down in the fancy category of dangerous explosives. Their difficulties on that subject were about on a par with those of fire insurance officials, who seemed often to classify the most dangerous parts of a place at the lowest rates and those which it was almost physically impossible to set on fire at the highest.

Dr. DUPRÉ, in reply, said that peroxide of sodium when kept by itself was perfectly harmless, but what he wanted to be more fully recognised than apparently it had been, was that when it was brought into contact with combustible substances it became exceedingly dangerous in the presence of water as well as of fire. He had often had occasion to draw public attention to the fact that when a danger was recognised it could be avoided, but if not known it led to disaster. The main point was to realise that under certain conditions there was danger, and then it could be easily avoided. He was always glad to accept any suggestion, and if he had given an explanation he was always ready to give it up if anybody else could suggest a better one. But throughout Mr. Tyler's remarks he did not recognise any suggestion as to how this explosion could have happened. If it was well packed in good boxes, and there was nothing else in it, how did the explosion occur? There was no doubt the explosion did take place. He was perfectly alive to the fact that sodium peroxide might contain metallic sodium, and no doubt a little was present in this

case, but the amount was so small that he attached no importance to it. But even if sodium were in it, how could it have gone off without something else being added? Of course it might if water got into it, but that landed one in the same difficulty. It was that which Mr. Tyrer had to explain. When dynamite was first introduced it was said it could only be exploded by a detonator, and many hundreds of lives were lost by trusting to that statement. People treated it as being non-explosive, and fatal accidents followed as a matter of course. In the same way, people were constantly coming to him with explosives which would not go off anyhow except just when they were wanted to; such statements were the cause of many accidents. He trusted that nothing he had said would be taken as a disparagement of peroxide of sodium or as casting a slur on the company who made it. That was far from his object. Peroxide of sodium was a useful substance, and he trusted it would be largely used, but he hoped the company would take warning and see that it was sent out in stronger tins and packed in such a manner that it was not possible for it to come in contact with combustible matters. If that was done it could be transported or stored for any length of time without any danger whatever.

*Meeting held Monday, March 5th, 1894.*

MR. WM. THORP IN THE CHAIR.

## THE COMMERCIAL PRODUCTION OF CHLORINE BY THE AMMONIA-SODA PROCESS.

BY F. HALE.

THE subject on which I wish to address you to-night is one of deep importance to the salt districts of this country, to our chemical trade, and therefore affects our commercial prosperity.

The competition between the old Leblanc process and the ammonia-soda processes for the production of soda and bleach which for years has been going on, has ended, I believe, in the complete success and victory of the latter over the former.

For some years past the old process was able to hold its own in having the monopoly of the bleaching trade, the ammonia-soda process being unable to make strong bleach.

All this is now altered, and pure and strong hydrochloric acid and chlorine can be produced by the new process much more readily and cheaply than by the old process of Leblanc.

The direct recovery of the hydrochloric acid from ammonium chloride without the use of lime has been the problem which chemists interested in the ammonia-soda process have had to grapple with. So long as lime was necessary for regenerating its ammonia, the waste of chlorine as calcium chloride occurred, and there seemed no likelihood from the great stability of calcium chloride of ever obtaining hydrochloric acid or chlorine as a practical and paying process on a manufacturing scale.

Mr. Mond has from time to time attempted the volatilisation of dry ammonium chloride, thereby forming nickel oxychloride and free ammonia as a basis for an industrial method of answering this problem; and in his later patents he uses magnesia made into marbles or pills with china-clay and an alkaline chloride, and piled in a Deacon furnace. The ammonium chloride is volatilised in fused chloride of zinc, and passed in the state of vapour through the marbles thus made. The ammonia is evolved and completely driven out of the retort by a neutral gas, which is also used for raising or lowering the temperature of the retort. Hydrochloric acid is given off at first from the magnesium chloride formed, and afterwards chlorine is obtained by hot

and dry air, to the extent of from 7—10 per cent., which he passes into a Deacon bleach chamber. The recovery of chlorine, however, in conjunction with this process, for the manufacture of strong bleach is still, I believe, a problem not yet solved.

The Verein für Chemische Industrie, at Mainz, have used manganese oxide with this object in view, in the hope that the two equations—

might work profitably on a large scale; but although the process has been protected, I have not heard that it has come up to the expectations of the patentees. The probable reasons for this will be explained below.

Other inventors have regarded the problem as hopeless. They have turned their attention to the recovery of the chlorine from the waste calcium chloride liquors, regarding the decomposition of ammonium chloride by means of lime as the only suitable reaction for the regeneration of the ammonia without loss.

Solvay has been most fruitful in patents in this direction, and the owners of these patents still hope, I hear, that the joint action of silica and alumina on calcium chloride at a high temperature in the presence of air will result in a commercial process for the recovery of the wasted chlorine.

The action is one which is well known, and was thought to be possible with the chlorides of the alkalis and alkaline earths by Talaude and Prudhomme many years ago. In its simplest form the change may be expressed thus:—

The substitution of magnesia for lime in decomposing the ammonium chloride liquors has also been thought a possible solution of the difficulty.

This process, which has been at work at Salindies since 1886, is now under the control of Messrs. Pechiney and Cie., and since magnesia has a tendency to form an oxychloride, which can be converted into oxide and chlorine when heated in air, the problem has been one which involved mechanical and engineering difficulties more than any novelty in the chemical reactions involved.

And lastly, Mr. Bell, of Middlesbrough, working on the lines of Schloesing, obtains his ammonia from solutions of ammonium chloride and magnesia, converts the resulting chloride of magnesium into grains by evaporation, and afterwards into anhydrous chloride of magnesium. From the first he gets hydrochloric acid gas by the downward percolation of steam, and from the second, chlorine by the downward percolation of air through the heated bed of magnesium chloride.

In the attempts which have thus been made to produce chlorine from ammonium chloride in the ammonia-soda process, none of them have been successful in producing strong and undiluted chlorine, fit for the manufacture of strong bleach, and this for the reason that air has been employed to obtain chlorine direct from the chloride formed and the air containing about 80 per cent. by volume of nitrogen.

These and other facts induced me to turn my attention to obtaining chlorine from the hydrochloric acid gas obtained from magnesium chloride through ammonium chloride. I have the honour of placing before you to-night the principles and practice by which this is accomplished, and I beg to invite your attention to the same, and your discussion thereon.

If ammonium chloride in powder is mixed with any of the monoxides in powder and gently heated, the ammonia is evolved and the chloride of the metal formed, water being at the same time produced.

The monoxide preferred is magnesium oxide, for the readiness with which it decomposes ammonium chloride, liberating ammonia, and for the ease and low temperature with which its chloride parts with hydrochloric acid when heated, and on the passage of steam through the same, as

mentioned hereafter. The higher oxides cannot be used for this purpose, as they form sesquioxides on the passage of air over their chlorides.

The sesquioxides thus formed cannot be used for the evolution of ammonia from the ammonium chloride without great loss of the ammonia.

The oxygen thus liberated reacts on the chloride formed, liberating chlorine, thus:—

The passage of the metal from the diad state, as chloride, to the tetrad condition, as oxide, accounts for this loss, and the liberated chlorine destroys a portion of the ammonia evolved—

and this to the extent of from 30 to 33 per cent. Their use, therefore, for liberation of the ammonia from ammonium chloride is quite out of the question.

In my earlier experiments this was a source of continual trouble, and one was inclined to believe that the evolution of the ammonia was governed by no law, until it was found that the sesquioxide was the sinner whose presence was the chief cause of the mischief, and was confirmed by trying nearly every other sesquioxide, with a similar result—a loss of from 30 to 33 per cent. ammonia.

The dioxide, as ( $\text{MnO}_2$ ), does not destroy the liberated ammonia.

We thus obtain another means of distinguishing the sesquioxide from the dioxide.

As the lower oxide ( $\text{MnO}$ ), and the higher ( $\text{Mn}_2\text{O}_3$ ), does not destroy the liberated ammonia, we cannot regard, therefore, the sesquioxide ( $\text{Mn}_2\text{O}_3$ ) as a mixture of the lower and higher oxides, and this theory, I think, must be given up, as it appears to be a true compound, thus:—

These higher oxides whose chlorides form sesquioxides on the passage of air or steam over them, and whose use is so disastrous in the evolution of the ammonia, become all-important in the evolution of chlorine from hydrochloric acid gas.

The above facts have compelled us to confine the evolution of the ammonia to the action of the monoxides, while the use of the peroxides or sesquioxides is confined to the evolution of strong chlorine from gaseous hydrochloric acid.

These facts enable us to obtain the ammonia without loss beyond unavoidable working losses, and the chlorine undiluted for the manufacture of strong bleach.

To accomplish this, it was necessary to obtain the hydrochloric acid pure, and in a fairly concentrated state. The best chloride for this purpose we found was chloride of magnesium,  $\text{MgCl}_2$ , whose readiness to evolve hydrochloric acid by heat, and superheated steam, is well known, and whose oxide gives good results for the ammonia.

The hydrochloric acid thus produced is obtained as a pure and strong continuous current, which might be used in the following manner:—

- (1.) It may be condensed in water, in the usual manner, producing the pure commercial acid.
- (2.) It may be condensed in a solution of calcic chloride, according to Wise's process, and afterwards obtained in a dry gaseous condition by heat: or, which is much preferred.
- (3.) It may be at once dried in strong sulphuric acid, descending in a tower or column, similar to the Glover tower, filled with pieces of coke, flint, &c., the gas entering the bottom, passing out dry at the top of the column.

The dry and gaseous hydrochloric acid produced by either of the above processes is heated up in a Cowper stove to about 550° C. It is then passed into a Deacon furnace containing peroxides made into balls or bricks by well known means, or used in thin layers in powder, when one third of the available chlorine is obtained strong, and practically free from hydrochloric acid.

The chlorine thus produced is freed from moisture by well-known means, and used for the production of strong bleach or mixed with dilute chlorine afterwards obtained from the chlorides formed.

Mn in the above equation might be manganese, cobalt, iron, bismuth, tin, lead, &c. Manganese oxide or mixtures of  $\text{Mn}_2\text{O}_3$ , Co, Co $_2\text{O}_3$ , Pb $_2\text{O}_3$ , give good results; the use of the first is preferred, mixed with some of the others, as the sesquioxide of manganese forms with them, manganates, and thus gives a larger yield of strong chlorine, thus:—

the remainder of the chlorine fixed in the above equation as chlorides is obtained by passing dry and heated air through the retorts, when dilute chlorine is given off, containing from 15—20 per cent. of chlorine mixed with air, and, if the drying of the marbles and the air has been carefully done, it will be free from hydrochloric acid, and be passed into the common chlorine conduit, and mixed with the strong chlorine obtained at first, and the round of operations recommenced, when this alternative process is used.

As a continuous process for the production of chlorine, I may carry on the above two reactions simultaneously, by passing a mixture of air and hydrochloric acid gas in proper proportions through the marbles in the cylinders. The gaseous mixture should first be dried in strong sulphuric acid and then passed through a Cowper stove, and heated to a temperature of about 500° C. to 550° C.; and if the drying has been carefully done, the gases on leaving the bottoms of the cylinders are, for practical purposes, free from hydrochloric acid, and after cooling and drying may be passed into a bleach chamber or otherwise used.

There are two methods of working throughout for the evolution of the ammonia and hydrochloric acid.

1. We may work the substances in powders throughout, both for the evolution of the ammonia and for the hydrochloric acid gas afterwards.

In this case, thin layers of the substances several inches deep in chambers are used, which are worked in series one above the other; Fig. 2 is a vertical section of such a chamber. The cylinder A is made of iron, and lined with

Fig. 1.

earthenware tiles or bricks. It is placed in a brick chamber which is heated by the furnace F, by flues *f f*, through which the gases from F circulate round the cylinder. By means of the stirrer S the contents can be mixed when

required, and from the hopper H the ammonium chloride is introduced at the plug P. The jets J admit superheated steam on to the mixture at the bottom of the retort.

The method of working is as follows:—

The ammonium chloride in powder is admitted from the hopper H, and passes down the tower T, till it meets the first open retort, into which it slides upon the opened door *d*, and is then caught and mixed with the oxide by the vane V, on the arm of the stirrer S, which is also kept in motion, to bring the mixture into contact with the hot sides of the retort, and to facilitate the passage of the gases formed (ammonia and hydrochloric acid) at the grated exit *s¹ s¹*, at the bottom of each of the retorts.

When the ammonia is evolved, superheated steam is admitted through the jets J J on to the mixture, and the stirring being continued, passages are thus opened for steam to penetrate into the interior of the mass, and for the hydrochloric acid gas evolved to pass away at the exit at the bottom, a current of pure and concentrated hydrochloric acid is evolved, which is dried and passed over the peroxides as described below, and the round of operations recommenced.

2. The second method is to work the mixtures in powder, during the evolution of the ammonia as above described, and then to agglomerate the resulting mixture of oxide and chloride. This is done by admitting through the jets J a spray of hot water, or one of a solution of ammonium chloride, on to the mixture, and by the stirrer moulding it into fragments or lumps, sufficient for the ready passage through it of superheated steam.

About two-thirds of the ammonium chloride is added at first as a powder, and the remainder in a saturated solution to agglomerate the mixture; most of the water used being evolved as hydrochloric acid afterwards.

The process is as follows:—

Starting at a temperature of 450° C. or 500° C., at which all the hydrochloric acid is evolved, cold air is passed

through the fragments, till they are reduced to about 200° C. The ammonium chloride in the form of powder is then passed into the retorts as above stated, through the hopper H. The mass is then well stirred with the stirrer S, the fragments and lumps of oxide readily reduced to powder, and mixed with the ammonium chloride, and the stirring is continued for the reason above stated. When the ammonia is nearly all given off, the temperature will have reached 200° C. A spray of a hot saturated solution of ammonium chloride is now allowed to enter the retorts from the jets J, and a continuous mixing causes the mixture to pass from the pasty condition to the state of grains or fragments, and the remainder of the ammonia is given off, and the retort cleared of the ammonia by a current of cold air. When this is completed, and the mass made permeable to the steam or air, the stirring is stopped. The heated air above mentioned is now passed through the fragments, and hydrochloric acid, steam, and air, are given off, which might be dried, and used for the continuous production of chlorine, as mentioned hereafter.

Superheated steam may afterwards be sent through the retort, to complete the reduction of the chloride, or a mixture of superheated steam and air.

When the hydrochloric acid is completely given off, the temperature is about 500° C., and the round of operations may be recommenced.

When the solution of ammonium chloride is added, the ammonia passes away by a pipe *t*, at the top of the tower T, through the safety valve *v*, which is raised also for the gases produced in the chambers to pass this way into the ammonia and hydrochloric acid conduit M N, when from too rapid an evolution in the chambers, or from stoppage, they cannot readily pass through the bottom exits *s¹ s¹*. When the mixture has assumed the form of fragments, the top exit is closed, the bottom being opened.

The hot gaseous hydrochloric acid evolved as above described, is dried in strong sulphuric acid in a Glover tower, heated up in a Cowper stove, and passed over a peroxide made into balls, or bricks, as in the Deacon process.

By carefully regulating the rate at which the gaseous hydrochloric acid passes over the peroxide, pure and undiluted chlorine is obtained to the extent of one-third of that contained in the hydrochloric acid, while the remaining two-thirds of the chlorine exists combined with the metal of the peroxide, as a metallic chloride, from which dilute chlorine and a regenerated oxide can be obtained by treatment with hot dry air or oxygen, or from which hydrochloric acid gas can be obtained by superheated steam, from which again chlorine can be obtained as before.

Figures 3 and 4 are respectively a plan and vertical section of the apparatus used. A and B are cylinders of

iron, enamelled or lined with tiles to resist the acid, and placed in a heated chamber of brick.

Each cylinder has a outlet pipe, or false bottom, D, for chlorine to pass away to the common conduit *c c*, in which the weak and the strong chlorine becomes mixed. P and P¹ are valves worked by a screw or lever. There are three inlet pipes to each cylinder, one each for the hydrochloric acid, air, and steam.

The peroxides in balls are placed inside the two cylinders A and B, or in a series of such cylinders, which are heated by the flues *f f*, circulating the gases from the furnace F.

Fig. 1.

In commencing work the valve P is opened and P' shut. Hot, dry hydrochloric acid is then admitted through C. A current of strong chlorine is evolved from the cylinder A, which passes through c, to be utilised as required.

When the absorption power of the balls in cylinder A, or in a series of such cylinders, is spent, the hydrochloric acid current is diverted into another cylinder, or series of such cylinders, and the valve P' is opened.

A current of superheated steam is now passed through S into A (or its series), and the hydrochloric acid evolved, dried, and passed through a Cowper stove to be heated up again, when it is passed into B (or its series) when about one-third of its chlorine is given off strong and pure.

To convert its monoxide into peroxide a current of hot, dry air is now passed into cylinder A (or its series), and superheated steam is sent through cylinder B (or its series) by means of steam pipe S', to free the fixed hydrochloric acid, which is dried, heated up as before to about 550° C., and passing into A (or its series), it gives off strong chlorine as before. The remaining chlorine in A as chloride may be got by air through the plug P, or neglected, as about four-fifths of the original chlorine in the hydrochloric acid used have been got strong and pure, and the series of operations may be recommenced by passing hot, dry air through A, to completely convert the monoxide into peroxide, and then sending through the cylinder (or its series) hot and dry hydrochloric acid as at first.

If the continuous process of producing chlorine is followed, a mixture of hot and dry air and hydrochloric acid gas in proper proportions, is passed through C from the ammonia retorts described above, or from elsewhere into both cylinders (or series of such), both the valves P and P' being opened, and a continuous current of dilute chlorine is obtained from the bottom of the cylinders, containing about 40 per cent. or more chlorine; and the necessary precautions of drying the gases being observed, it may at once be used after cooling for the production of strong bleach.

The alternative process of using hot and dry air where superheated steam is used above may be followed with more or less advantage.

The apparatus above described, in which the mixtures in thin layers are used in powders throughout for the ammonia and hydrochloric acid, may be used with great advantage for the evolution of chlorine from hydrochloric acid gas, by using the oxide in powders of small depth but great surface, as in the apparatus in Fig. 2, of which Fig 1 is a sectional plan.

## NOTES ON LITHOGRAPHIC VARNISH.

BY F. H. LEEDS.

Lithographic varnish is the principal ingredient of the vehicle used to suspend the various pigments employed in the manufacture of painters' inks, but while its name might give rise to the idea that it is only used in lithography, this is by no means the case, as it occupies a similar position in the preparation of the better classes of ink made for printing from letterpress, and the modern photographic process block. It is a product obtained by the treatment of linseed oil alone, differing from painters' boiled oil by its containing no driers. It forms a perfectly clear, transparent substance, only slightly darker, when of the best quality, than the raw oil, but often having a faintly reddish tinge, and possessing always, when prepared by fire heat, a more or less strongly marked green fluorescence. From a curious prejudice painters generally prefer a very dark oil for their use, apparently believing that it is more likely to be genuine, or that it will work better, but printers and printing-ink makers are wiser, and, whether making lithographic varnish or other products containing driers, strive hard to keep their oils as pale as possible, which is obviously of importance, especially when light and transparent pigments are to be ground into them.

Lithographic varnish is met with in five and sometimes six different degrees of consistency, from an oil that is only slightly more viscid than raw linseed, to one which will yield between the fingers at ordinary temperatures a "string" of two or more feet in length. Such a product as the latter is known as "extra strong" lithographic varnish; then in order of decreasing "strength" come "strong," "middle," "thin," "tint," and occasionally "thin-tint." These varnishes—except in the case of the "burnt oil" described below—are valuable simply for their viscosity or "body," which enables the stiffer varieties to suspend pigments of very high specific gravity, since the drying power of the thin or tint is not appreciably greater than that of raw linseed oil, while as the boiling progresses this becomes much weaker, until the extra-strong varnish can hardly be said to dry at all.

The ordinary process of manufacture is simple, although it requires the exercise of some care to prevent a dangerous fire: the oil is heated in iron pans or boilers, which for the better qualities of varnish are enamelled inside, set over a small fire so arranged as to be capable of instant withdrawal. The pan is about two-thirds filled with raw oil, and the heat raised cautiously at first till the water is all driven off. If much effervescence take place and scum rise to the surface, the oil is too new to yield a good product, and had best be put aside for a time to settle; but a fair varnish can be obtained by carefully skimming off the froth (the so-called albuminous matter) as it rises. When all has been removed, the temperature is increased to from 500° to 550° F., and the oil allowed to boil quietly until the proper strength is reached, which is usually determined by taking a few drops out on a palette knife, dropping them on to a piece of cold metal, and testing the tackiness with the finger. This proving satisfactory, the fire is withdrawn, and the varnish allowed to rest for an hour or mere to give time for the "foots" to settle, when it is run or poured off into the storage vessels. During the process of boiling a considerable quantity of very irritating fumes are given off, so that the pot should be provided with a hood to carry them away, while in populous neighbourhoods it will probably become necessary to lead them through a small fire into the shaft of the works. The time required to reach any particular strength is not a fixed quantity, decreasing considerably as the oil gets older, beside varying inversely with the temperature employed. However, seeing that by increasing the heat, the colour of the finished varnish is darkened, it is often advisable to work more slowly at a lower temperature. The loss of weight on boiling also varies a good deal, decreasing, as would be expected, with the age of the oil, the amount being about 3 to 10 per cent.

For certain purposes, a fairly quick drying varnish, which when in bulk will skin over strongly in 24 to 48 hours at ordinary temperatures, is obtained by heating the raw oil

up to the flashing point, and allowing it to burn quietly with constant stirring until the desired strength is reached—the product being known as “burnt oil.” Linseed varnish is also prepared by steam heat, coupled with an air blast and mechanical agitation, but details of this method of manufacture cannot be given.

Another method consists essentially in treating linseed oil with oxygen for some hours at a moderate heat. In this process, the oil gains instead of losing in weight, two samples made from an inferior East Indian oil (sp. gr. 0.929) showing an increase of 3 and 5 per cent. in weight, and possessing gravities of 0.996 and 1.002 respectively. Unfortunately, these samples, which were prepared in the early days of the process, were diminished materially in value by their persistent and unpleasant odour, which would have prevented their use for any but the commonest kinds of out-of-door work. Recently the process has been improved, and Messrs. Wood and Bedford, of Leeds, the present licensees, have kindly treated some of the same oil from which the ordinary varnishes were made, preparing two qualities, one of the same strength as the middle, and the other lying between the strong and the extra-strong lithographic varnishes. They form very pale oils, no darker than the original, not quite so clear as the others, free from the fluorescence mentioned above, but still possessing a stronger and more disagreeable smell than the products obtained by fire heat alone.

From the foregoing it will be seen that age is one of the most important characteristics of linseed oil for varnish makers: in fact the difference in yield, colour, and particularly in fuel consumption, between a varnish made from a “mature” or “well-tanked” oil when first received from the crushers, and from the same oil after it has again been tanked only for a month or so, is very noticeable. Regarding the valuation of oils specially for boiling purposes—assuming their genuineness—not much information has hitherto been found obtainable by laboratory tests alone; generally speaking, the higher the specific gravity the better the oil, but samples should always be boiled in porcelain with the aid of a nitrogen thermometer, at a temperature of about 250° to 300° C., and the colour and percentage loss of the varnish noted, as with care the results approximate very closely to those obtained on the large scale.

The constants in Table I. have been obtained from varnish prepared by fire heat: the tint, thin, burnt thin, and middle being made from the Calcutta oil whose figures are given for comparison, the strong and extra strong coming from another East Indian oil, the constants of which were not noted. The specific gravities were taken on amounts of 15.0–200 grms., but are at the temperature of 15° C. The iodine absorptions are the figures obtained at six hours, the free acid is calculated, as usual, as oleic, and the “Fahrian-acids” are those insoluble in petroleum ether obtained on carrying out the process described by him, *Zeits. f. angew. Chem.* 1891, 540; this *Journal* 1891, 1015.

In Table II. are given the figures of the acids from these varnishes after removal of the unsaponifiable matter. Appliances were not at hand to prepare them in an atmosphere free from oxygen, but to eliminate as far as possible this source of error, they were all dried in flasks under uniform conditions as to temperature and time, and they were examined within 48 hours of extraction. That they were partially oxidised, however, is shown by the fact that in all cases on weighing they were found to be 94–95 per cent. of the oil saponified. The specific gravities were taken by the method of floating the acids in alcohol, and the neutralization numbers by titrating them with aqueous alkali.

Tables III. and IV. contain the corresponding figures obtained from the oxygenated oils and their acids, and also those from some of the same sample of raw linseed oil, which, to compare the effect of drying, had been exposed in a flat dish to a moderate current of air at 45° C. for about five weeks, care being taken daily to break up any skin formed, and thoroughly mix up the whole mass. In this time, the oil assumed a jelly-like condition, lumps of comparatively hard material and skin, alternating with a small amount of oil of the consistency of middle varnish. The oxidised oils are much more readily soluble in alcohol, and, especially the thinner one, possess more strongly marked drying powers than the ordinary varnishes, and they are saturated with gas which caused them to effervesce on heating, and from which they could not perfectly be freed at the temperature of the water oven, even by prolonged heating. For this reason the determination of the specific gravities was not so satisfactory as in the case of the former var-

nishes, as the flasks had to be heated for several hours to 125° C., and from the marked discolouration of the oils, it is probable that some change in their constitution had taken place. On titrating their alcoholic solutions with aqueous alkali, a point was found where the pink colour of the phenolphthalein remained after a vigorous shaking (the first of the figures given in the third column), but disappeared on standing for a short time protected from the air, the higher amount of acid recorded being obtained by adding the alkali a few drops at a time until the colour remained constant for two or three minutes. The other constants also show that the treatment with oxygen alters the constitution of the oil far more than simple boiling, and it was noticed that although the varnishes themselves are very pale, they darken, as previously mentioned, somewhat on heating and very considerably during saponification, so that the extracted acids are much deeper in colour than those from even the extra strong lithographic varnish in Table I., while on weighing only 84—85 per cent. (*cf. ante*) of the oil was recovered.

The small amount of unsaponifiable matter in all of these varnishes shows that the "difficulty" (this Journal, 1892, 848) of estimating the amount of rosin oil present as an adulterant is not so great as might be supposed, assuming that the latter is employed in its refined state, and if the crude oil containing resin acids (which from its colour is unlikely) or rosin itself has been used, Twitchell's process is available.

It may be observed here that while Lewkowitsch (this Journal, 1893, 505) and Twitchell agree in taking 346—348 as the average combining weight of the resin acids from rosin, this is only the figure obtained by titrating the original rosin itself with its 6—7 per cent. of unsaponifiable matter, whereas the "Twitchelling" is usually applied to the mixed acids after the unsaponifiable matter has been removed; and these acids have been found in a large number of cases to have an average acid number of 183, *i.e.*, a combining weight of 306. Working with this figure, or by preference gravimetrically, repeating a second time the treatment with hydrochloric acid gas whenever the extracted resins did not appear to be perfectly brittle or had the least smell of linseed oil, and considering them on finally weighing to represent 93 per cent. of the rosin, the author has obtained, when working on known mixtures, results within 1 per cent. of the truth, and preliminary experiments on mixtures of linseed oil or varnish and resins other than rosin show that the process will in all probability be found serviceable for, such separations also.

In conclusion, I have to record my indebtedness to the directors of Messrs. John Kidd and Co., Limited, London, in whose laboratory these results have been obtained.

## AN AUTOMATIC ALARM FOR WATER OVENS AND WATER BATHS.

BY CHARLES S. S. WEBSTER, F.I.C., F.C.S.

The apparatus consists of an upright cylindrical brass tube A, surmounted by a movable cap B, the upper end of which is plugged with a circular disc of ebonite C, having a fine

Fig. 1.

Fig. 2.

hole drilled in its centre, through which passes loosely the straight brass wire D (No. 25\*), bent at right angles above the disc, and extending below to the bottom of the tube.†

\* Numbers on standard wire gauge.

† Half-inch brass tube was used 5 ins. long.

On to the lower end of this wire is threaded the cork F, used as a float, and shaped as in the illustration (the largest part of this float is shown in section c). The wire is bent up and firmly fixed to the bottom of the float.

The reason for cutting the cork in this manner is obvious, *i.e.*, to avoid capillary attraction. A very small piece of brass foil is soldered to the wire at F, thus preventing the float from rising too high.

To the side of the cap is fixed the platinum spring G (the shape of which is seen at g). This spring is bent so that its point shall fall on the platinum button H, forming a make and break arrangement. It has been found most satisfactory to use platinum just twice the thickness of the ordinary analytical foil (*i.e.*,  $\frac{1}{1000}$  inch). The hole in the tube at K releases any steam pressure.

To fix the apparatus a large hole is cut in the top of the oven or outer ring of the water bath, and a perforated cork inserted, through which the tube is passed until it almost touches the bottom of the oven. The wires I and J are then connected with the electric bell and battery. The water in the oven will raise the float so that the spring G will be lifted, as seen in Fig. 2, and the bell will not ring.

When the water by evaporation has been reduced to the depth of about one inch the spring will be lowered so that its point will touch the platinum button, Fig. 1. The contact completes the circuit, and therefore brings into play any suitable electrical contrivance either for cutting off gas, supplying water to the oven, or ringing a bell so that the deficiency of water may be made known.

A more permanent float can be made with a modern bullet coating, which has been previously reduced in a lathe, and having three guiding wires at its lower end.

A somewhat similar apparatus may be made with a glass tube fitted with a cork at the top instead of the ebonite disc, and a circular wooden platform above to which the fittings are attached, but it is of course not so substantial as the brass pattern.

Meeting held March 7th, 1894.

MR. EUSTACE CAREY IN THE CHAIR.

## METHODS FOR THE RECTIFICATION OF OIL OF VITRIOL.

BY FRANK TATE.

RECTIFIED oil of vitriol is so widely used in the chemical and allied industries that I have ventured to think a short review of some of the methods at present employed and recently proposed for rectification may be of some interest to this Society.

As no doubt you are all aware, Prof. Lunge, in the last edition of his work on sulphuric acid and alkali, has brought us very closely up to date, and I am afraid that I have very little to add that is new. I trust, however, the few notes I have put together may be deemed worthy of a discussion which may prove of greater service to the Society than the paper itself.

Within the last ten or twelve years many suggestions and improvements have been put forward, and, as a result, the concentration of vitriol to the higher strengths is to-day a much simpler and more economical process than it was a few years since.

The only apparatus used by the majority of manufacturers in the United Kingdom up to a comparatively recent time, and indeed now very widely used, consisted of the familiar glass retorts resting on sand, in flanged cast-iron pots built into brickwork, and arranged in sets or benches in numbers as required, each retort having a separate fireplace.

Platinum was practically the only rival of glass, and, whilst glass continued to be the favourite material in this country, platinum was very generally adopted on the Continent.

I will not weary you with details of the various ideas patented in the last decade, but it will be clear to all those perusing the specifications that the chief object has been to bring about a continuous process in some form, and so obviate the great loss of time and fuel that necessarily attends the working of an intermittent process such as the old method of working glass retorts.

The Gridley, or as perhaps it is more generally termed, the Chance process, was one of the earliest steps in this direction.

Following it are proposals for continuous processes using a variety of materials, *e.g.*, various forms of platinum apparatus, retorts of iron with protection and without protection, iron lined with enamel or porcelain, brick-lined pans built into a furnace connected with brick-packed towers, &c.

At the present day, as far as I am aware, manufacturers have before them a choice of materials and systems which may be shortly classified as follows:—

1. Platinum—
  - (a) Platinum *per se*.
  - (b) Platinum gold-plated.
2. Glass and porcelain—
  - (a) Intermittent: without cooling pans, with cooling pans.
  - (b) Continuous: Chance's, Veitch's, Webb's, Levinstein's.
3. Iron—
  - (a) Iron *per se*.
  - (b) Enamelled iron (Dyson's).
4. The Kessler furnace system.

A manufacturer, in deciding on his apparatus, has to consider the following, amongst other points: 1st, the purpose for which the acid is required; 2nd, the strength of the acid available for concentration; 3rd, the space at his disposal for building; 4th, the first cost of the plant; 5th, the cost of labour, fuel, and wear and tear in working the plant.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

### SESSION 1894.

April 4th.—Mr. J. Henry Brown. "The Treatment of Cupreous Iron Pyrites as carried on at Portuguese Mines."

In considering the first point, both the purity and strength of the finished acid are important. If the acid is to be used in the textile trades for such processes as the bleaching and dyeing of cotton or woollen goods, or in the production of colours, &c., a plant composed of a material not liable to taint the acid must be aimed at, and platinum, glass, or porcelain at present claim first consideration.

The attaining of high strengths without undue wear and tear of plant is also of great importance for many purposes.

If the question is one of producing a quantity at a low cost, rather than purity of product, I think we shall find that iron has some claims.

I purpose to describe, very briefly, some of the methods at present in use for concentration, and to append some figures of costs.

**Platinum.**—Without attempting to more than refer to some of the legion of proposals as to form and arrangement of platinum plants, I think I may take it that the chief systems in use to-day are the Faure and Kessler, the Prentice, and the Delplace systems.

The Faure and Kessler system is a combination of platinum dishes with lead covers. It is very fully described by Professor Lange (Vol. I, p. 712, 725).

In the Prentice system the chief consideration is the enlargement of the heating surface by the use of a corrugated still bottom, which, it is said, increases the heating surface in the proportion of 1·57 to 1.

The system of Delplace consists of platinum stills working in series at different levels, the top still being fed with the weakest acid, the highest concentration being attained in the lowest still. This still is fed with the acid from the higher pan. The distillate from the lower pans also undergoes concentration through the series.

A form of still suggested by Desmoutis is shallow in depth, and has a bottom fitted with concentric partitions, giving a longer travel through the still.

A few details as to the cost of some of the platinum apparatus may, perhaps, prove interesting.

When working with the Faure and Kessler system, *i.e.*, platinum pans with lead covers kept cool with water (pans about 40½ ins. diameter), a system of two such pans is estimated to produce in a day of 24 hours from 11 to 12 tons of acid of 92 to 93 per cent., or about 8 tons of 95 to 96 per cent. Acid of a higher strength than 97 per cent. is not economically made by this system, as the wear and tear of the hoods is very great.

The weight of the platinum may be about 1,350 ozs. troy, which at, say, 40s. per oz., means 2,700*l.*, and to this price must be added the cost of the lead covers, the setting, and the vapour-condensing apparatus.

Using the Delplace system to produce 11 to 12 tons per day of 24 hours (of 92 to 93 per cent.) or 5 to 6 tons of 97 to 98 per cent., two platinum pans of a width of 19½ ins. and length of 58½ inches, with platinum covers and fittings weighing about 1,800 ounces troy, are needed, which, at 40s. per oz., equals 3,600*l.* A modified Delplace system has been suggested, in which one of the platinum pans has a leaden cover. This arrangement for the production of the same quantity of acid would reduce the cost of the platinum to 2,700*l.*

An arrangement of the Prentice system, using a combination of platinum pans with lead covers, and one closed platinum still, would cost rather more for the same production of acid than the modified Delplace system.

The labour on a platinum plant is of necessity small; the fuel amounts to about 3 to 4 cwt. per ton of 92–93 per cent. acid produced, but is increased to 5 to 6 cwt. if the higher strengths are aimed at.

In 1891 Mr. Heraeus, of Hanau, Germany, patented the plating of platinum with gold for use in the manufacture of vessels for the rectification of vitriol and other purposes. He proposed to heat the sheet of platinum above the melting temperature of gold, and to run over the same a layer of gold of suitable thickness. The details of this process you will find in his specification. He claims, amongst other things, that the platinum stills coated in this way will last a much longer time than ordinary stills.

Through the courtesy of Messrs. Domier, of London, I have received the following record of some results of the working of gold-lined pans from Mr. Heraeus:—

"At the beginning of February 1891 I supplied to a German works a piece of gold-platinum sheet—0·25 parts platinum, 0·005 parts gold—which was inserted in the bottom of a pan made of platinum only.

"After some time the pure platinum part of this pan became then through continual use, I took the pan out and it was found that on the gold-platinum sheet I had inserted no action of the acid whatever was visible, and so my idea was conclusively proved to be right.

"It was at first thought that it would be sufficient to coat the apparatus inside with gold only as far as the acid reached, or perhaps a little higher, and all my first orders were for pans made this way. I received orders from 11 works for plants—two on the Prentice system, two on the Faure-Kessler system, and the remainder on the Delplace system."

"These apparatus did not fulfil all expectations, especially those which were only coated with the absolutely necessary quantities of gold."

"Two others were stopped after working eight to ten months on account of the bottoms being burnt through in consequence of formation of crust."

"Five others are still working."

"Concentrating apparatus only partly gold-coated are not to be recommended, as at the place where the platinum and gold-platinum have been joined electrical action sets in and will destroy the platinum. The saving which might be effected by having apparatus only partly of gold-platinum is, therefore, more than neutralised by this loss, and I do not intend making any more partly gold-coated pans, but only such as are entirely coated with gold."

"These perfected apparatus have proved highly satisfactory in every respect, and the loss of metal in concentrating high percentage sulphuric acid is so infinitesimal that further improvements are practically out of the question."

"On the Continent and in America there are about 50 of these pans at work at present, but only from a few of these factories have I been able to get the exact loss, as these pans are, perhaps, only taken out once during the year."

"The results up till now surpass all expectation, and prove that the loss of metal in working gold-platinum pans is about one-twentieth of what is lost in working pans of platinum only. The following are some results:—

No. 1. One Prentice apparatus entirely made of gold, worked from the beginning of May 1892 to middle of June 1893 uninterruptedly, concentrating principally 66 Beaumé acid. Quantity not stated.

Total loss 39 grms., equal to about 0·08 gm. per day.

No. 2. One Delplace apparatus, only the lower part being made of platinum gold.

Production: 950 tons, 92 — 93 per cent.  $H_2SO_4$

" 491 " 96 " "

Loss per ton 0·11 gm.

No doubt a better result would have been obtained if the whole pan had been made of platinum gold.

No. 3. One Delplace apparatus, only the lower part made of platinum gold, concentrated 1,438 tons, 66 Beaumé acid. Loss per ton 0·17 gm.

No. 4. One Delplace apparatus—originally only the lower part made of platinum gold—concentrated acid of 92 to 93 per cent.  $H_2SO_4$ . Loss 0·04 gm. per ton.

This pan was returned to the works, and a new one made entirely of platinum gold supplied in its place. Since then 1,195 tons of acid have been concentrated, and it is impossible to state any loss in weight.

No. 5. One pan worked from the 14th July to 30th December, principally 97 to 98 per cent. acid. The daily concentration of about 6 tons of this high percentage gave a daily loss of 0·35 grms., equal to about 0·66 gm. per ton.

No. 6. Faure-Kessler pans coated only with gold as far as the acid reaches. In this case a better result would have been obtained if the pans had been made entirely of platinum-gold. A first result of a partly coated pan, working 93 per cent.  $H_2SO_4$  gave a loss of 0·45 grms. per ton.

The latest result with a pan made entirely of platinum-gold working 95.8 per cent.  $\text{H}_2\text{SO}_4$ , gave a loss of 0.2 gram. per ton acid.

No. 7. System same as No. 6, working acid of 93 per cent.  $\text{H}_2\text{SO}_4$ , formerly lost, using partly coated apparatus, 0.4 gram. per ton. The latest result, using apparatus entirely coated with gold—loss equal to 0.01 gram. per ton.

Quite lately one of the pans on the Delplace system was taken out and weighed.

The apparatus was entirely made of platinum-gold, and concentrated during nine months, working uninterruptedly—

1,728 tons of 95.95 per cent.  $\text{H}_2\text{SO}_4$   
135 " 96.96 " " "

The total loss on weight of the apparatus was 55 grms., equal to 0.03 gram. per ton of acid.

As a comparison of cost working with gold and without gold, taking the price of gold as 93.6s. per oz. troy and the cost of the platinum at 40s. per oz. troy, working on the Delplace system modified with gold 3,022l. 16s., without gold 2,766l. With the Faure and Kessler system with gold 2,999l. 12s., without gold 2,700l. The Prentice system with gold 3,081l. 19s., without 2,894l.

It will be seen that the first cost of platinum-gold apparatus is a serious consideration, but to firms with capital a heavy first cost simply means so much interest on the capital invested per ton of acid produced. Platinum plant of course occupies very small space, but the production of the very highest strength of sulphuric acid without undue wear and tear is perhaps a debatable point.

**Glass.**—In the working of the old form of glass plant the glass may be worked in one of two ways, 1st. working daily—the finished acid of the one day being run into cooling jars on the following morning before charging the retorts; or working on alternate days—two nights and a day being allowed for cooling before siphoning into earboys. If the acid is used in the works of the producer it can, of course be run into some form of cooler on the morning following the day of working, and the retorts be worked daily.

The first cost of a glass plant to produce about 10 tons per day of 24 hours may be roughly estimated at 800l. to 1,000l. inclusive of a condensing apparatus. As regards the fuel used there seems to be considerable diversity of opinion. I have seen statements giving the amount of fuel necessary to concentrate from 152° Tw. to 168°—170° Tw. varying in amount from 18 cwt. to 4 cwt. per ton of finished acid. The figure, using a fair class of fuel, will probably be 13 to 14 cwt. per ton of acid. The labour may be reckoned at 1s. to 4s. 6d. per ton finished acid.

**Wear and Tear.**—This varies very much according to the quality of the glasses and the workmen. For instance, Luty (this Journal, 1893, pages 153—154) tells us that in a plant directed at the Mulheim works for a daily output of three and a half tons of 169° Tw. vitriol per day, 35 glasses were broken during the first 14 months of working. This is at the rate of about two glasses per five months. My own experience is that this cost may be very much reduced, and I have known a plant of over 40 glasses run for some months without a single breakage. The building was a good one, and the glasses carefully protected from draught, and the foreman one of the most careful and conscientious men I have ever met in a chemical works.

On other parts of the plant the wear and tear is very slight, the iron pots, lasting, if properly set, for a very long time, and the brickwork requiring very occasional repairs.

**Chance Plant.**—This requires no description. For the production of 23 to 25 tons of strong vitriol per week the cost is about 300l., including about 100l. for a suitable shed.

One set of Chance glasses, four in number, will produce 10 to 12 tons of rectified vitriol per week from acid of 148°—156° Tw. Acid at 95 per cent. is readily obtained by this process, but some time is lost in getting up to 97 per cent. The cost of labour upon the plant is much less than on the old system, say, about 2s. to 3s. per ton of finished acid. The cost of fuel varies to some extent and depends upon the mode of firing—whether by means of a gas-producer or by hand-firing and ordinary fire-grate. It is of course considerably less than the intermittent system. I should put it down at about two-thirds of the

cost of the old system, and from 10 to 12 cwt. per ton of finished acid. The breakages of the glasses is not great, say, one glass to 180 to 200 tons of finished vitriol. About 1s. per ton will cover the general wear and tear. It is necessary in order to keep down breakages to work with clean acid containing as little soluble and suspended matter as possible. The plant requires a good building, but occupies little space. The labour should be intelligent and thoroughly skilled.

Mr. George Veitch of Crieff in 1889 protected an arrangement consisting of hard Bohemian or English glass retorts mounted in a line on a stepped terrace within a fire flue, all connected by a lip or spout between each of the retorts, so that the acid is made to flow continuously through the series from the retort on the highest step to that on the lowest. The specification described in this arrangement, which includes a drawing, is of considerable interest. I hoped to have had some results of working to put before you, but unfortunately they are not to hand, and I cannot say with what success the plant has worked.

In 1891, Mr. T. G. Webb of Manchester introduced a system in which beakers or cylindrical glass vessels are arranged in series in a furnace chamber. These glasses are open at the top with a lip or spout for overflow at one side. In each of these vessels is a glass tube presenting a funnel-mouth to receive the overflow from the vessels above, and extending down to the bottom of the vessel below, with a slit or other outlet at the lower end. The furnace chamber is covered by a sloping or stepped roof of iron plate in which are cast holes through which the upper part of the beakers project. Above the tops of the beakers is a roof of slabs with outlets leading to the condensing apparatus. The furnace chamber is fired by one or more fires, the fuel used being coke.

The hot gases from the fire play upon the beakers below the iron plate. The weak sulphuric acid is supplied to the highest beaker, flowing to the bottom of the beaker through the tube, gradually causing an overflow of the acid by the lip into the tube of the next beaker, and flowing from beaker to beaker, becoming more and more concentrated till at last it flows into the cooler. The cooler consists of porcelain dishes surrounded by cold vitriol, which is contained in a vessel surrounded by cold water. The plant can be arranged in one of two forms, either in the cascade arrangement, as just described, or in the horizontal arrangement, in which syphons carry the acid from one vessel to the other.

Mr. Levinstein of Manchester, in 1892, brought forward an interesting arrangement in which the acid is caused to traverse a descending series of vessels in a type of apparatus in some respects, at least, similar to the one I have just described.

Reverting to Webb's patent, the cost of plant for a run of 14 glasses, exclusive of royalty, is from 60l. to 100l., according to the elaboration of details. The plant occupies very little space, two runs of 14 glasses, or a smaller number, are generally arranged side by side, working as one set. Mr. Webb commences with glasses, but is now using porcelain as the material of which his beakers are made. From some figures that have been kindly placed before me from an independent source, a run of 14 vessels will produce a carboy of 14.9 Tw. acid, from 148° Tw. acid, per hour using less than half a cwt. of coke per hour.

One man can manage four runs easily, and in this way the labour is only about 2d. per carboy. The cost of labour, of course, depends entirely on the number of runs in work in the same building. One man can manage four runs, but it will take one man to manage one run also. Fourteen glasses will produce 5 to 6 tons per week of strong acid from 120° Tw. acid, or 11 to 12 tons per week from 148° Tw. acid. The fuel is put down as about 3 to 4 cwt. of coke per ton of rectified vitriol when working with 148° Tw. acid, or 6 to 7 cwt. when working with 120° Tw. acid.

**Wear and Tear.**—Working with glasses by this system the wear and tear, I understand, is considerable. With the porcelain vessels it seems to be very much reduced, and a gentleman who has been working some time with the process informs me that he has had no breakages since he replaced the bottom two or three glasses by porcelain vessels. Of course there is some wear and tear upon the brickwork,

but it should not be heavy. The flow of the acid is controlled by means of a thermometer inserted in one of the beakers some three or four removed from the bottom beaker.

With this plant any strength of acid may be boiled down without the use of a leaden pan for previous concentration. Mixed acids, such as we meet with in explosive works, can be readily concentrated with such an apparatus as this to very high strengths. There should be little or no loss of acid apart from the question of dissociation and loss through the condenser. Any acid spilt by overflow of the beakers or by breakages of the beakers is caught in suitably arranged gutters and returned into process again. In case of breakage only a very short time is necessary to replace the broken vessel. What has been said as regards cost of fuel and labour in reference to Mr. Webb's plant applies also to the plant which Mr. Levinstein claims.

Another form of porcelain apparatus is that of capsules arranged in cascade as proposed by M. Negrier, and described by Prof. Lunge. I have endeavoured to obtain some details of the working of this plant, but have been unsuccessful.

**Iron.**—Without entering into the history of the use of iron pans for concentrating acid, which would at least include the patents of Gridley and Menzies, it will be sufficient for me to remind you that for many years cast-iron pans have been used with more or less success for concentrating vitriol. I have received one communication with reference to the use of a wrought-iron pot  $\frac{3}{4}$  of an inch thick, about 6 ft. diameter, and 4 ft. deep, which some years ago was bought second-hand from a tar distiller. A mixture of sulphuric and nitric acids of about 159° Tw. has been concentrated in this pot for a long period, the nitric acid being recovered, and sulphuric acid of 169° to 170° Tw. being produced at a very low cost for fuel and labour. This pot is still working.

I believe cast-iron pots are in use in many places for concentrating vitriol from 148° Tw. to a high strength. The larger pots are about 9 feet diameter and 6 feet deep, 2 ins. thick, and weighing 10 to 11 tons. The pot is covered with a cast-iron lid. It is set in brickwork, and fired with a single fire. If the acid is run in at about 148° Tw. in 28 to 30 hours, it will be at about 96 per cent. Fresh acid is run in from time to time. Twelve tons of 96 per cent. acid can be finished in such a pot. If the acid is not required very pure, 12 hours is sufficient for settling and cooling, and the pot can be worked about seven times per fortnight of 14 days, producing 42 tons of acid per week. The fuel consumed amounts to about 2 cwt. per ton of finished acid. The labour can be reduced to 1s. per ton, and need not be as skilled as with other plants. Wear and tear is heavy, and amounts to from 2s. to 4s. per ton of finished acid. A pot will finish from 500 to 600 tons of acid before it is necessary to replace it. The pot has to be sludged out from time to time, and this means a loss of acid in the form of iron salts, &c., to from 4 to 5 per cent. on the finished acid. The cost of the pot is about 60*l.*, of the cover 10*l.*, brickwork setting about 30*l.* One cover outlasts three or four pots, and, of course, the old pot can be sold for scrap, and will be worth from 10*l.* to 15*l.* The plant requires no costly building, and occupies little space. The highest strength acid can be produced, and the most impure acids can be dealt with. Acids containing matters in solution and suspension which would cause considerable trouble in other plants can be readily treated in the iron pot.

**Enamelled Iron.**—In 1883, William West of Denver, through Mr. W. P. Thompson, brought forward an apparatus for concentrating sulphuric acid in an enamelled or porcelain lined retort. The process was to be a continuous one. I am not in a position to speak about the success of this, as I have no facts before me. Mr. Dyson of Manchester has recently brought out another form of apparatus having enamelled iron as its material. The material employed is of special manufacture. The plant consists of a series of enamelled iron vessels through which sulphuric acid passes, being rendered more and more concentrated until it reaches the end of the series, where it passes into a suitable cooler. According to particulars supplied to me by Mr. Dyson, for a plant producing 21 tons per week of

seven days concentrating from 52° B. to 66° B., the ground space required for a single run of 18 retorts is 20 sq. ft., and for the cooler 12 $\frac{1}{2}$  sq. ft. The elevation from the floor line is 8 ft. 6 ins. The cost of the plant, for the production of 42 tons a week, is about 500*l.* The fuel used is common coke, with a consumption of 6 cwt. per ton of 112° Tw. acid. The cost of labour is the wages of a man working day and night. I can say nothing of the cost of wear and tear on this plant. I believe it has been a work for some time, but for how long I cannot say. I can say what results, as regards wear and tear, I am not in a position to speak. As in the case of the Webb plant there need be no loss of acid, as suitable gutters are provided to catch any spilt, every part of the plant is readily accessible, each vessel is separate and distinct, and can be renewed very easily and at a small cost.

**The Kessler Furnace System.**—In 1884 M. Kessler of Clermont-Ferrand, France, patented an invention for the concentration of sulphuric acid by means of heated gas acting on large or greatly developed surfaces of sulphuric acid, so as to readily concentrate the acid to its maximum density at a low temperature. The troughs or compartments in which the concentration was to be effected were to be made of any cheap acid-resisting material able to withstand the necessary temperature.

It is impossible in this paper to do justice to this very interesting suggestion. I can only shortly describe the apparatus, which consists of two chief parts:—the one spoken of as the saturator, which consists of a large rectangular trough made of material that cannot be attacked by the hot concentrated acid (such as pumice or sandstone), the joints being made of a cement also of acid-resisting material. The trough is divided by a series of parallel partitions into compartments, some of which receive the gases which arrive through cast-iron pipes, which gases then pass into other passages raising or grazing the layer of acid which occupies the bottom of the saturator and rising into the upper portion of the apparatus. The upper portion of this arrangement is placed either directly or laterally above the saturator, from which it receives its gas and to which it sends its acid. It consists of a series of horizontal compartments placed one above another pierced with openings which are covered with caps, which force the acid to blow strongly upon the liquid or to furrow it across. The acid proceeds horizontally in a shallow layer from one wall to the other, where it meets with the return pipes, which carry it down to the lower compartment by an arrangement somewhat similar to ordinary compartment stills. The upper portion of the apparatus may be constructed entirely of lead, but preferable, if pure acid is necessary, of free-stone or earthenware. The hot gases are exhausted through the apparatus by some arrangement producing a vacuum. The fuel used is small coke from gasworks, which is too fine for use for other purposes. The consumption, it is said, does not exceed one and three-quarter cwt. per ton of acid coming direct from the chambers at 52° B. This consumption is a little increased if any fuel is used for producing a vacuum. The labour with a special stove, in which the coke furnace receives the fuel necessary for 24 hours' work, is hardly anything. The apparatus has been in operation for two years at Clermont-Ferrand, and a further apparatus, it is said, is about to be erected. For these particulars as regards this very interesting system of Kessler's, I am indebted to a paper in the "Moniteur Scientifique" by M. Gerdier. Before closing these remarks I think I should do well to state that attention has been called in the Inspector's report on alkali works to what appears to be an increased escape of gas from the condensers when working with continuous processes other than platinum. I wish in conclusion to acknowledge the kindness of Messrs. Webb, Levinstein, and Dyson in affording me opportunities of viewing their plants.

#### DISCUSSION.

Mr. M. L. DAVIES said that the best method of rectification depended upon the purpose for which the acid was required; that determined the percentage and colour. He was speaking without experience of the Kessler oven, but

imagined that great care should be exercised, or the acid would become discoloured. For some purposes that would be a great detriment.

In this country a large amount of rectified vitriol used was only 92-97 per cent.; in America it was almost exclusively that percentage. With regard to wear and tear, he did not think there was much difficulty with any process in securing 95 per cent. of monohydrate, but the moment one attempted to get beyond that, difficulties arose either in the construction of the plant or in the consumption of fuel and further, there was a considerable reduction of the output. In some experiments he found, when trying to make 97 per cent. acid, the output had been reduced by one-third.

In regard to the form or system employed, he was acquainted with most of the platinum stills, but would favour the Faure and Kessler system because of its ready access for repair and also because of the small amount of acid it held. The secret of concentration to his mind was to have a small depth of acid in any still. That he thought was defeated by some of the other processes.

As to comparison between glass and platinum, he could hardly think to which to give the preference for ordinary strengths, but for very high strengths glass had the advantage. He had had some experience with glass, and with regard to Chance's had a fair experiment made and found that he got results agreeing with Messrs. Chance's figures in output and consumption of coal gas; but in consequence of the high price of gas in Liverpool, the cost of fuel was much heavier than with slack in the platinum installation.

As to the cost of material, he thought that his experience would hardly agree with the lecturer's statement that 1s. per ton would cover the cost of glass.

Mr. TATE replied that from recent experience 1s. covered wear and tear of the plant other than of glass; he thought that he had mentioned that the glass amounted to one glass per 180 to 200 tons of finished acid; one retort cost 25s.

Mr. DAVIES, continuing, said he had found from figures that the loss of material over 12 months in platinum was 3s. per ton finished vitriol, and by glass 5s. 6d., which latter was accounted for by the heavy breakages. He did not wish to infer that this was due to the poorness of the material. They had it very well cased in, but each time a stoppage was made by the breaking of a retort, the others frequently cracked at the boiling surface owing to the admission of cold air, and it became a question whether it would not be better to renew the whole of the retorts at once.

In regard to the loss of platinum, he was looking over an old book recently and found that in 1875 when platinum pans were brought into Liverpool for the first time, several pans showed a loss of about only 0.3 grms. per ton; following it down to the present time he found a gradual increase and it appeared to him that the quality of the metal had depreciated. The quicker destruction of pans may be due to the presence of iridium and other members of the platinum group, which would render the metal more brittle and its elasticity would in consequence be reduced, which is a very important matter, especially when using pans of 40 ins. diameter and upwards. Occasionally good results were yet obtained, for instance, he found in 1890 for a matter of something like 500 tons the loss was only 0.34 grms. per ton.

He had tried several experiments to get 97 per cent. monohydrate, but with a tremendous loss of something like 20 grms. of platinum per ton. It was not only the finishing pan that suffered, but the first also, which usually scarcely suffers at all. Owing to the heavy firing and a much reduced feed, the vitriol in each pan became of the same high specific gravity and that accounted for the parallel loss.

Referring to the consumption of fuel, he did not think Mr. Tate's information was correct, that was to say, he did not find that one got reliable information from men working comparative experiments. They seemed to have an idea that the latest introduction should be the best, and unless one was very careful to check the men, the figures obtained were apt to be misleading. From his

own experience the average consumption of fuel per ton finished rectified 95 per cent. acid, which included concentration from 100° to 168° Tw.,—was about 5 cwt. of good Lancashire slack. It will be well to remember the difference between Lancashire, Staffordshire and Scotch varieties. Some of the coke figures he thought were too high.

Mr. A. E. FLETCHER asked Mr. Tate if he had examined the glass which was commonly used. It struck him as strange that the manufacturers should be satisfied with the ordinary soft lead glass. In every case he had examined the glass was of that description. There was no great difficulty in getting a harder glass. Still, as far as he knew, most glasses that were used were of the soft glass type. He had often expressed surprise that there was not more effort to get the hard flint glass, which would be less easily attacked by acid, more able to resist mechanical strain, and less liable to crack with change of temperature. Did Mr. Tate know any reason why that glass was not used?

Mr. R. F. CARPENTER said in the latter part of Mr. Tate's paper, mention had been made of the work of Inspectors under the Alkali Acts, in estimating the loss of acid during rectifying. He had had many of these continuous as well as intermittent processes under his purview, but had not made any definite quantitative test of the acid lost, so as to compare the one type of process with the other in this respect; such a comparison required that the speed of the exit flues be determined by the anemometer, and in the last report he guarded himself from straining the results of "total acidity as  $\text{SO}_3$ " tests further than they would bear. He would mention one danger that some of the continuous processes described by Mr. Tate appeared to him to be under, viz., those in which a comparatively small amount of liquor was in process at one time, surrounded by heated brick flues, which retained a large reserve of heat. Firing in such processes was controlled by thermometric indications, and the run of acid and the firing were regulated thereby. With slight alterations of run or of heat supply, he had found conditions established which led to a very considerable loss of acid by volatilisation and dissociation. The thermometers in use required themselves to be carefully tested from time to time, else the same losses might be going on when the man in charge of the plant might deem that all was going on right. In the modified Delplace platinum plant the hydrometer in the distillate from the strong pan or retort gave immediate indication of too heavy firing and the remedy then for over-heating was equally immediate in its action.

In the description of the Kessler process, p. 36 of the January number of the Journal, it was stated that rectification to 66° B. could be attained at a temperature not exceeding 170° C. None of the other processes mentioned by Mr. Tate could claim that the process finished at that low temperature; and as regards dissociation loss the superposed "recuperator" seemed specially adapted for arresting this anhydride if volatilisation took place, as it most probably would in the saturator under the influence of fuel gases entering and bubbling through the acid at 500° C. Mr. Levinstein had shown how readily the anhydrous acid was absorbed in strong acid near the point of monohydrate such as would be found in the lower compartment of the recuperator. But whether this system could be largely adopted must depend, as Mr. Davies stated, on the uses to which the acid was to be subsequently applied; some customers requiring the acid to be perfectly bright and colourless. He thought it would not do to claim too much for the method of rectifying in cast iron as regards the highest strengths, however useful it might be for works requiring acid of 95 to 95½ per cent. It had been found that in attempting by continued firing to get a higher strength that the loss by volatilisation and dissociation was greater than the concentration, so that the acid in the pan actually became weaker, as he had stated in the last report; this did not seem to be the case with platinum, though the action on the platinum certainly increased then very rapidly indeed.

Mr. E. K. MURRAY said he thought there was a good deal of misunderstanding as to the breakage of glass retorts. It depended very much upon the quality of glass in the retorts. They had had glass retorts that had broken almost daily and others had lasted nearly a year. Their experience had always been that there was great variation in the quality of glass and platinum that one worked with. In the case Mr. Davies spoke of, there was at that time great breakage and cost of material. He was trying to make extra strong concentrated sulphuric acid—a strength about 98 per cent. He thought that would account for the heavy cost of breakages at that time. His own experience was that on the whole for concentrated acid, about 93 per cent. or 94 per cent., the Faure and Kessler apparatus was the most economical in regard to fuel and wear and tear. The wear and tear which one did not work to concentrate beyond this strength was under  $\frac{1}{2}$  gram of platinum per ton of rectified acid. The fuel was extremely low, but when one spoke about the quantity of fuel, one must know the strength of the acid delivered to the apparatus, and the strength to which it was concentrated. Unless they had those two factors before them it was absolutely ridiculous to make any comparison as to quantity of fuel used. Every inventor always tried to give the best results, and not the whole truth. The Faure and Kessler new method was extremely interesting, but there were some objections to it, otherwise they might have tried it. What surprised him was the number of these new inventions, while the saving was so small. It showed there had been enormous competition in the sale of sulphuric acid, and everybody had been trying to get strong sulphuric acid at the lowest possible cost. A large amount of money had been spent on experiments, and now after 20 or 30 years' experimenting with platinum and glass, there was not much to choose between the various methods and the choice depended upon local conditions.

Mr. NICHOLSON said that in regard to the discoloration of the acid produced in the Kessler process he had received a sample of the acid produced from Mr. Kessler and it was as clear as spring water.

Mr. TATE, in reply, said he quite agreed with Mr. Davies that one of the chief features to be considered was the purpose for which the acid was to be used. If the pure acid was required, one must have a suitable plant that would not taint the acid. If, on the other hand, they had to work up an impure acid containing matters in solution and suspension, then, he thought, they would find glass practically out of the question, as also platinum, owing to the formation of deposits and crusts, and consequent wear and tear.

As to the discoloration of acid produced by the Kessler furnace, Mr. Nicholson had already referred to that.

Mr. Davies had said the strength of acid in this country was usually 92 per cent. to 93 per cent. That might be so, but he knew that in Lancashire a great deal of stronger acid was sold. He thought that Mr. Davies' experience of breakages with the Chinese plant was rather unique. It must have been an unfortunate season. The figures he had been able to obtain were certainly very much lower than Mr. Davies' figures. As regards the loss of platinum, the figures he had mentioned referred to plants in which gold-plated platinum had been used.

As to how far the quality of glass affected the wear and tear of glass plants, he regretted he was unable to give any information. He had used glass made in various works and found that some makers could supply a glass which would stand excellently. He had known times when a plant had run for months without breakage, but that he thought was due to careful annealing of the glasses and the watchfulness of the workman.

## ESTIMATION OF CADMIUM.

BY MAX MURRAY.

The following examination of the usual methods for the gravimetric determination of cadmium was carried out under the supervision of Prof. F. C. Clark, at the analytical laboratory of the Polytechnic School, Zurich. The time at my disposal was too limited to allow an exhaustive comparison of the various methods, and I do not claim to have made such, but I found a few facts not hitherto recorded, which greatly influence the accuracy of the method of determination of cadmium in the form of oxide and which may prove useful to others.

Of the three methods usually recommended for the gravimetric estimation of cadmium, a few words will suffice to show my way of applying them.

(1) *Determination of cadmium in form of oxide by previous precipitation with sodium carbonate*.—This is the method to which I have paid most attention. Its apparent simplicity led me to adopt it as a standard method with which to compare the other methods, until I discovered its errors. The cadmium is precipitated from its solution with a solution of sodium carbonate. The precipitate of cadmium carbonate is washed, dried, and separated as completely as possible from the filter paper, then ignited in a porcelain crucible, the filter paper being burnt in a platinum coil, and added to the contents of the crucible.

(2) *Determination of cadmium in the form of sulphide*. (Ros's method).—The cadmium is precipitated from its acid solution by sulphuretted hydrogen and the precipitate ignited in a current of hydrogen gas.

(3) *Electrolytic methods*. The several electrolytic methods differ chiefly in the solvent employed. I used (1) solution of KCN, (2) dilute H<sub>2</sub>SO<sub>4</sub>, (3) solution of ammonium oxalate. In either case a large platinum dish served as the anode, the anode being formed of a platinum spiral. The current employed was measured by an ordinary voltmeter, and was of such strength as to yield from 0.2 to 0.5 cc. of electrolytic gas per minute. The deposited metal was washed with alcohol and ether, dried, and weighed.

For comparing these various methods I employed a solution No. 1 of cadmium sulphate containing about 7.4 grms. of crystallised cadmium sulphate in 2 litres. For each determination a few cc. of this solution were employed. I give the results of two series of determinations made by the first method, i.e., by precipitation with sodium carbonate.

### I. CARBONATE METHOD.

50 cc. gave—

(a.) 0.0850 grms. Cd.	= 0.071 grms. Cd.
(b.) 0.0851 " "	= 0.0717 " "
(c.) 0.0854 " "	= 0.0719 " "

### II. CARBONATE METHOD.

50 cc. gave—

(a.) 0.0801 grms. Cd.	= 0.070 grms. Cd.
(b.) 0.0807 " "	= 0.0703 " "
(c.) 0.0802 " "	= 0.0702 " "

whereas the electrolytic method yielded for the same solution:—

50 cc. gave:—

(a.) 0.0794 grms. Cd.
(b.) 0.0799 " "

It will be seen that the results of each series are practically identical, but that the results of the two series, which ought to have been alike, differ from each other, and the results of the carbonate method are all of them much lower than those obtained by the electrolytic method.

In consequence of these conflicting results the electrolytic methods were more fully investigated, and were found to give identical results whatever modification was made in the solvent.

A solution (No. 2) containing 7 grms. of crystallised sulphate of cadmium in two litres of water was employed for these and the following experiments:—

## ELECTROLYTIC METHOD.

Solvent—	In 50 cc. found.	Grms. Cd.	Mean.
KCN.....	(1.) 0.0750 (2.) 0.0764	0.0753	0.0753
H <sub>2</sub> SO <sub>4</sub> .....	(1.) 0.0763 (2.) 0.0766		
Ammonium oxalate.....	1. 0.0771 2. 0.0765	0.0768	

The same solution yielded by Rose's method in 50 cc. 0.0782 grms. Cd., corresponding to 0.0764 grms. Cd.

By the carbonate method very inconsistent results were obtained. 50 cc. of the solution yielded:—

1.	0.0755 grms. CdO.
	0.0828 " "
	0.0893 " "
	0.0771 " "

The absolute consistency of the results obtained by the electrolytic method justifies their adoption as normal results.

I next endeavoured to find the causes of error of the carbonate method. The most obvious source of error might be expected to be found in the comparative ease with which cadmium oxide is reduced to the metallic state, and then volatilised, particularly that part of the oxide which, still adhering to the filter-paper, is ignited in contact with it in the platinum spiral. An addition of ammonia nitrate to the filter paper failed to improve the results.

I then tried the following modification of the carbonate process. The first precipitate of cadmium carbonate was dissolved in pure nitric acid, and the solution evaporated to dryness on a water-bath in a large porcelain crucible (previously tared). The cadmium nitrate, which formed a white cake at the bottom of the crucible, was gently heated and thus converted into oxide.

The oxide obtained by this ignition of the nitrate formed a perfectly compact black film, adhering to the crucible, from which it could only be removed by solution in acids, whilst the oxide obtained by ignition of the carbonate was a red-brown earthy powder.

The following results were obtained by this method:—

In 50 cc. of the solution used for the previous experiments (No. 2 solution) were found:

1.	0.0870 grms. CdO = 0.0761 grms. Cd.
(2.)	0.0897 " " = 0.0759 " "

These results agree fairly with those obtained by electro-deposition, but the agreement is more apparent than real, for the cadmium oxide was found to contain a small but quite appreciable quantity of sulphate. The reagents employed were quite pure, so that the sulphate must be due to the precipitation of a small quantity of basic sulphate with the original carbonate.

This error might be obviated or diminished by repeated solution and precipitation, but the method loses much of its simplicity. Whatever other faults the original method with sodium carbonate may have, it is a curious fact that the oxide obtained by the ignition of the carbonate does not contain any cadmium sulphate. Since the precipitated cadmium carbonate must have contained sulphate, this can only be explained by dissociation of the sulphate during the ignition of the carbonate, which does not take place during the ignition of the nitrate. Considering the great difference in the physical properties of the two oxides, such a difference in their chemical behaviour is quite conceivable.

The following modification of the process was next tried:—

The cadmium was precipitated as carbonate washed and dried. As much as possible of this precipitate was scraped into a weighed crucible and converted into oxide by gentle ignition. The oxide was free from sulphate. This was weighed by itself (a).

The filter paper was treated with pure nitric acid and the resulting solution and risings brought into a large porcelain crucible and evaporated to dryness. The dry nitrate was gently heated and the oxide weighed (b). The oxide

obtained in this way probably contained some sulphate, but the amount of oxide is so small a portion of that obtained under (a) that the error cannot be appreciable.

The following results were thus obtained:—

50 cc. of solution No. 2 yielded—

	Precipitate (a).	Filter (b).	Sum a + b =	Cadmium.
(1.)	0.0629	0.0209	0.0838 =	0.0753 grms.
(2.)	0.0485	0.0346	0.0831 =	0.0727 "
(3.)	0.0605	0.0231	0.0836 =	0.0731 "

It will be seen that the results are still too low. If, however, the precipitate (a) is considered to be Cd<sub>2</sub>O instead of CdO, and the results be calculated on this assumption, they will be found to be correct and to agree with the results obtained by electrolysis. This fact led to the final modification, consisting in heating the oxide (a) in a stream of oxygen until no further increase in weight takes place (maximum weight (c)).

The above precipitates (a) heated in a current of oxygen to constant weight finally furnished the following results:—

	G.	(b)	G + b.	Cd.
(1.)	0.0595	0.0209	0.0805 =	0.0765 grms.
(2.)	0.0725	0.0346	0.0871 =	0.0762 "
(3.)	0.0637	0.0231	0.0868 =	0.0760 "

These results are identical with those obtained above by the electrolytic methods and by Rose's method.

The method to be recommended is the following:—

Precipitate the cadmium as carbonate with sodium carbonate, filter, wash and dry. Detach as much as possible of the precipitate from the filter, and heat it in a porcelain crucible in a stream of oxygen. Heat gently at first, gradually raise the temperature, but never use a blast. Dissolve the small quantity of precipitate remaining on the filter in nitric acid, evaporate to dryness and convert into oxide by gently heating. Weigh this oxide by itself.

It is probable that a current of air might replace the oxygen, but I have not made the experiment.

With respect to the other methods I will add but few words.

Rose's method gave good results, but I found it too tedious for general use. It is important to remember the two allotropic forms of cadmium sulphide as regards ease of manipulation. If the precipitation with H<sub>2</sub>S takes place in dilute acid solution the precipitate is yellow, very fine and consequently difficult to wash. If the cadmium is precipitated from a concentrated acid solution the sulphide is reddish brown, very dense, and easy to work with.

I also made an attempt to adapt *Vollhard's method* for the estimation of zinc to the estimation of cadmium. Vollhard's method consists in evaporating the solution of zinc chloride to dryness in a platinum dish, mixing it with pure mercuric oxide and a little water, evaporating again and then gently heating. Mercuric chloride and the excess of mercuric oxide volatilise and zinc oxide remains behind. Whilst the method is satisfactory for zinc it has not proved useful for cadmium. Cadmium chloride is so volatile that it escapes with the mercuric chloride, and the results are much too low. When cadmium nitrate was used the presence of sulphate seriously interfered with the accuracy and the method was more complicated owing to the introduction of extra reagents and manipulations.

Of all the methods examined, preference must undoubtedly be given to the electrolytic methods for their simplicity, cleanliness, and accuracy. What I have said above sufficiently describes the method. Cadmium does not oxidise, and with a moderate amount of care very satisfactory results can be obtained. The chief precautions are to use dilute solutions and weak currents. Of the three

solvents I have enumerated I prefer the use of dilute sulphuric acid, because it yields accurate results, evolves no poisonous fumes and does not require the regulation of temperature.

Quite apart from the interest which the observations on the oxide of cadmium possess with respect to the quantitative estimation of the metal, they raise the question as to the composition of the oxide obtained by the ignition of the carbonate.

The existence of an oxide of the composition  $Cd_2O$  has often been stated as doubtful. The facts I have communicated above seem greatly to strengthen the case for its existence.

The oxide obtained by ignition of the carbonate of cadmium is a dark brown powder. By oxidation in a current of oxygen as described it still retains its colour and its form. Prolonged heating with an ordinary flame, even after discontinuing the stream of oxygen, does not cause any change. When heated with the blast a gradual loss of weight takes place, accompanied by a gradual change from the brown modification to the black. The loss in weight thus incurred bears, however, no definite relation to the original weight of the oxide, and cannot be compensated for by again heating in a current of oxygen. Indeed, the loss subsequently is so great that it cannot be otherwise accounted for than by volatilisation of cadmium.

The comparative ease with which the original oxide absorbs oxygen speaks more for its being an oxide  $Cd_2O$  than a mere mixture of the normal oxide  $CdO$  with metallic cadmium, since metallic cadmium is very difficult to oxidise.

The loss incurred on heating the normal oxide over the blast appears to be due not to a reduction to  $Cd_2O$ , but to the direct volatilisation of the oxide as such.

## SUGAR BEETROOT GROWING EXPERIMENTS IN ENGLAND, SCOTLAND, AND IRELAND IN 1893.

BY G. SCHACK SOMMER, F.R.S.

(Abstract.)

The author has continued his experiments on the growth of sugar beetroot for the fifth consecutive year. (This Journal, 1890, 153; 1891, 318; and 1893, 233.) The results, of which the following is a summary, are detailed in "Sugar," 1894, VI., pp. 43-47. They again give most satisfactory proofs of the possibility of successfully raising a larger crop of good rich quality roots in this country, and corroborate the fact that both our soil and climate are favourable to the growth of sugar beetroots. The results of 1893 show that, despite the large size of the roots obtained in England, the purity coefficient is wonderfully good, and that the percentage of sugar per acre is larger than that recorded by Mr. Licht for Germany. The Scotch roots also show a high purity coefficient.

### SUMMARY RESULTS OF THE EXPERIMENTAL CULTIVATION OF SUGAR BEETROOTS IN ENGLAND, SCOTLAND, AND IRELAND IN THE YEAR 1893.

### THE SAMPLING OF MATERIALS.

BY T. CLARKSON, A.R.S.M., ETC.

EVERYONE who is connected with the chemical industries appreciates the importance of sampling. The selection of a small but truly representative portion may be regarded as the first step in determining the composition of a large quantity of material.

To obtain a sample by hand necessitates much time, labour, and care. Consequently it is not surprising that the portion obtained is frequently inaccurate and non-representative. It is to be regretted that the word sample is often used in a loose manner as a general term for a small portion of material. It would avoid confusion if its use was restricted to such small portions as are truly representative of the bulk.

It is generally acknowledged by chemists that making every allowance for different methods of analysis, the differences in analyses are more often due to defective sampling than to subsequent mistakes in manipulation.

A complete investigation of the theory and practice of sampling is beyond the scope of this paper, but we may briefly examine the principles affecting the selection of a small true average portion from a large bulk of material. It is scarcely necessary to state that all solid materials which have to be sampled must be crushed or otherwise obtained in a more or less granular form. The degree of fineness of the material before taking the first sample is important. If the bulk is very large, say a cargo of phosphates or pyrites, the pieces may be proportionately large, provided that the first sample selected is of fair size, say from 2 to 10 per cent. of the whole according to the material, but before further reducing the weight of the sample the size of the pieces must be reduced upon the basis that there must be a certain minimum number of particles in a sample, below which it is unsafe to go if the representative character of the sample is not to be endangered. What this minimum number is, must be determined experimentally for each class of materials. As an illustration of this principle, assume that there are 50 bricks of a material designated by A, 25 of another material B, 15 of C, and 10 of D. Dividing these numbers by their greatest common measure, namely, 5, there would be 10 of A, 5 of B, 3 of C, 2 of D. These bricks, if taken together, would be a representative sample of the original lot, and would be one-fifth of its weight. To attempt to reduce the bulk

of the sample below this point without sub-dividing the pieces would clearly result in destroying the sample. This also illustrates the difficulty of properly sampling a large bulk of waste material containing only a few particles of value. As, for example, in the case of some gold ores, consisting of a large amount of barren quartz containing a few small nuggets or specks of metal. In such a case it is imperative to crush it all very fine and sift out any flattened nuggets that will not crush. The sifted material may then be sampled and the coarse residue reported separately.

The thoroughness of the mixing of the bulk is very important. If the mixing is perfect, then any small portion taken at random would be representative; in fact, this would be the test of the perfection of the mixing. If materials were well mixed sampling would be greatly simplified, but this is seldom the case. Generally the composition of materials is far from uniform throughout the bulk, and in some cases, owing to the differences in the size and specific gravity of the various constituents, there is a great tendency for them to separate, the fine and heavy material going to the bottom.

To obtain a fair sample of a heap of material it is necessary to take some of the richest, some of the poorest, and some of all the intermediate values of parts, and these, too, in the same proportion as that in which they occur in the bulk. Thus, if there are twice as many rich pieces as poor ones in the bulk, there must be twice as many in the sample, and so for the other different values of pieces. The difference in the size of the pieces is also an important factor, as the fine material is almost invariably different in value to the coarse; sometimes one is richer, and sometimes the other; hence it is also necessary in selecting a sample to have the fine and the coarse in the same proportion as in the bulk.

From this it will be now clear, even to those previously unfamiliar with the rigid requirements of exact sampling, that the work, if done by hand, demands great care and conscientious judgment, besides considerable time and labour.

So much for the theory of sampling.

Assuming that the material, whatever it may be, has been crushed, and that it has been decided what percentage of it to take as a sample, the next question is how best to take the percentage so as to ensure getting a fair proportion of all the various sizes and qualities of the particles making up the bulk?

This brings us to the practice of sampling.

It would be well first to consider the methods of hand sampling, then the question of machine sampling (which will be illustrated by a practical demonstration), and finally will be discussed some general considerations relative to the most efficient and economical manner of dealing with large bulks, referring particularly to chemical manures and fertilisers.

In hand-sampling a cargo or large heap it is customary to take portions from all over the exposed parts. Sometimes the sampler in dealing with the cargo will wait until it is half discharged before making a selection in order to have a larger portion of the heart of the material exposed.

The sampler must exercise care and judgment to take the coarse and fine parts in the correct proportions, and it is doubtless in the exercise of this discretion that mistakes will occur.

Sometimes a sample car load is made up by taking, say one bag or one bucketful in fifty, but however the first sample may be selected the subsequent treatment of it to obtain the final sample is much the same. If the original material is coarse the first sample must be crushed finer and then carefully mixed and quartered on a clean and dry floor. The best method of hand-mixing appears to be to build up a cone by carefully placing each spadeful of material exactly upon the centre of the first spadeful, thus causing the constituents of each spade to flow down all sides of the cone. When the cone is completed it is carefully levelled down into a flat, circular layer a few inches thick, and across this two lines are drawn at right angles to divide up the circle into four equal segments. Two opposite segments are then shovelled out and built up into a smaller cone, which is treated in precisely the same

manner as before. The process of coning and quartering with any necessary further crushing is repeated until the sample is sufficiently small. This method gives very good results if proper care is taken and sufficient time and labour allowed.

Another hand method of reducing the size of the first sample consists in taking lumps from all over the material, which is spread out in a layer a few inches thick, but care must be exercised that in taking the bits the scoop goes right through the layer, otherwise a fair proportion of the finer parts, which generally contrive to get to the bottom, will not be obtained.

Another method often employed in sampling ores, matte, &c., consists in building the material into a rectangular flat heap, which for a quantity of about 100 tons would be from 2 to 3 feet thick. The pile is then opened by shovelling out two channels at right angles across the centre of it, the material shovelled out being thrown upon the rest. From each of the eight faces or sections of the pile thus obtained, is removed a portion by "rising" the shovel from bottom to top, the total quantity thus removed being about 10 per cent. of the pile.

After crushing this sample finer it is formed into a smaller rectangular pile, which may be turned over two or three times, and then channelled and sampled as before.

It is also very important to notice the general regulations for taking samples of fertilisers and food-stuffs which have been prepared by the Board of Agriculture. Clause 13 of these regulations specifies a certain minimum number of bags or packages which are to be taken as a first sample for quantities not exceeding ten hundredweight up to quantities exceeding five tons. In the former case it is two, and in the latter ten.

The size or weight of the bags or packages is not stated, but if they were unusually small the sampler would probably take a larger number of them. It would perhaps be safer to specify for certain percentages of the weight of the total quantity to be taken as a first sample. In clause 15, which refers to the sampling of bulks, no figures are given as a guide to the size of the first sample, nor is any particular mode of selection specified; the whole bulk may or may not be turned over. If it is not turned over and the first sample is made up of outside portions only, the result can scarcely be regarded as satisfactory. To avoid great discrepancies between the sampling of various persons it might be well to specify a certain minimum percentage of the bulk to be taken for the first sample, and also that the bulk be turned over and portions taken before and after turning over; or that the method as described above for ores be adopted.

The method of reducing the first sample to convenient size, as specified in clause 14, is a very old method and on first reading these regulations the author was somewhat surprised that such an old method had not been superseded. It is certainly simple, but, like all methods of hand-sampling, something is left to the personal equation, and this is exactly what it is desirable to avoid if the results obtained by different persons are to agree.

Another drawback to this method is that the material is exposed for a much longer time—see clause 22—than is necessary. There is thus a risk of alteration in the composition of the material, and the representative character of the sample may be lost.

The disadvantages of hand-sampling have given birth to several mechanical contrivances which have been designed to save labour and time and to ensure a greater degree of accuracy than the average of hand work.

Mechanical sampling is based upon the idea of intercepting or cutting out a portion of a stream of material. This may be done either by taking part of the stream continuously or the whole stream intermittently.

Before describing the various systems of machine or automatic sampling which are illustrated in the diagram, it is well to consider what are the essential conditions to be fulfilled by an efficient sampling appliance.

Firstly, it must select with certainty and precision a truly representative portion from the material that is passed through it, independently of the differences of the size and

specific gravity of the individual pieces of material; and secondly, it must not require any skill or care in the operator. It must also be of great simplicity and the possibility of the lodgement of material must be avoided. The machine must be adjustable so that large or small samples may be obtained as required. The machine must be capable of taking independent duplicate samples, that are exactly alike in all respects, and the accuracy of the sampling must not be affected, however imperfectly the material may be mixed.

Refer now to the diagram which represents graphically the methods of cutting adopted in five different systems of mechanical sampling. A short portion of a stream of material is shown in each case with shaded parts representing the portions of the stream removed for the sample, and the portions which are discarded. Figs. 1 and 2 illustrate the action of the fixed and oscillating spouts, which cut out a narrow

# A COMPARISON OF FIVE SYSTEMS OF MECHANICAL SAMPLING.

Fig. 1. Fig. 2. Fig. 3. Fig. 4. Fig. 5.

Section along B-C.

groove of material continuously from a solid stream, but, owing to the irregular composition of the stream and the segregation of fine and coarse material in different parts, the sampling proved unsatisfactory. This resulted some people to conclude that the only way to secure accuracy was by intercepting the whole stream for a part of the time. Several machines were designed to this end, but only in one case apparently was the result secured. Fig. 3 explains the action of several machines, the essential part of which consists in a reversible deflecting plate for diverting the stream intermittently. It is seen that as the time occupied in reversing the deflecting plate is appreciable, more of one side of the stream is intercepted than of the other, and as the two sides of the stream are unlikely to be of equal quality the selection is therefore partial. In the device whose action is illustrated in Fig. 4 the last-named defect is eliminated, for the cutting is not made by a reversible plate, but by a revolving box or compartment which passes periodically through the stream. The portions of material thus selected fall immediately, and consequently in a pulsating stream, on to a second apportioner similar to the former, but revolving in the opposite direction and at three times the speed. If this second apportioner operated upon a continuous stream it would make three actual cuts for each one of the former; but as the stream is pulsating, or intermittent, this result is not secured, and some of the cuts can only be regarded as theoretical and never actually take place. The same

observations apply to the third apportioner, which revolves in the original direction, but at nine times the speed.

The net result is that the ultimate sample is made up of small portions of the original stream, which occur widely apart, and between which a large portion of material of unknown composition is discarded. Another drawback to this machine is the lodgement of material in difficultly accessible places, for the removal of which a strong jet of air or water is necessary. Thus, there is a danger of contamination between different parcels of material. It is also found that the machine does not work with such precision as will enable a definitely required percentage to be cut out with accuracy, the variations above or below the correct weight amounting frequently to 60 or 70 per cent.

All the machines described above are of American origin, but the next one is English.

Fig. 5 represents the essential features and *modus operandi* of a sampling machine used by the author. The upper part of the figure represents the nozzle of a rotating hopper which receives the material. This delivers a solid rotating stream of material at A, which is immediately split upon the point of the cone D, thus becoming a hollow rotating cylinder of falling material. From this annular rotating stream two or more samples are cut continuously by means of segmentally-shaped spouts, which pass completely through the stream. The effect of the rotation of the stream of material is to make each spout cut out a helical path such as shown, and if two spouts are used, as is commonly the case, a double helix results. Each of the cuts is clearly quite independent of the other.

THE LABORATORY DIVIDER.

supported a feeding platform or supplementary storage hopper. In the centre will be seen the cone upon which the stream of material splits. The segmental cutting spouts are hidden from view, but the delivery ends of the spouts appear as projections upon each side of the centre column. The bulk of the material, after the samples have been taken, passes down through the column on to a lower floor or into a wagon. In each machine there are two sets of spouts, one set

The edges of the segments are made truly radial, as shown in the plan, which represents a section on the line B C. It will be clear that the percentage of material removed by each spout depends simply upon the angle between the spout edges: that is, if 10 per cent. is required the angle must be  $36^\circ$ , or 10 per cent. of the circle; and for 5 per cent.  $18^\circ$ , and so on. It is found by actual experiments that if the spout edges are made to these angles, the weights of each of the samples cut out agrees with the calculated percentage with remarkable accuracy. There is no appreciable difference indicated by an ordinary pair of scales between either of the samples and the theoretical percentage, although the variation in the sizes and weights of the pieces of material in the bulk may be great. As a further test of the precision of the apparatus, if the differently sized constituents of each of the duplicate samples are separated by sieves, it is found that there is the same percentage of the various sizes in each sample as in the bulk. Thus, for example, if the original material contains 20 per cent. of sand, 50 per cent. of wheat, and 30 per cent. of peas, then each of the samples will contain 20 per cent. of sand, 50 per cent. of wheat, and 30 per cent. of peas. It would be practically impossible to sample such a material by hand, owing to the unmixability of the constituents, but this creates no difficulty in machine-sampling.

Fig. 6 represents an external view of the machine, with the sample boxes removed. The rotating hopper runs upon a ball bearing, which is supported on three stout columns. The turning of the hopper may be effected by either hand or power, acting through the bevel wheels shown. Above the hopper is a stationary guard ring upon which may be

Fig. 7.

VERTICAL SECTION.

taking duplicates of 10 per cent. each, and the other duplicates of 5 per cent. each. Only one set is in operation at once, but it is contrived that the change from one set to the other can be made almost instantaneously by moving a lever. When 5 per cent. or 10 per cent. is too large a quantity for a sample, it is again passed through the machine, or it may pass through a smaller machine placed lower down. In some cases, where the material is fine and fairly uniform, a

sample of only 1 per cent. can be safely taken at one cut, and if this sample is again passed through, a reduction in volume of 10,000 to 1 is accomplished by the two operations. This can be easily done with the tailings coming direct from gold-stamp mills.

After a sample has been obtained it usually happens that several persons wish to have a portion of it for separate analysis; thus the sample may be divided into three parts, one being for the buyer, another for the seller, and a third for the district analyst. Sometimes six or more distinct samples are wanted, and, in order that the results of the separate tests and analyses may agree, it is clearly essential that all the samples should be identical—that each should have a fair share of the fine and the coarse, the rich and the poor, the heavy and the light particles.

To accomplish this, the divider shown in section in Fig. 7 has been prepared. It is identical in principle with the sampler; that is, the material is formed into a rotating annular stream by means of a rotating hopper and cone, but instead of only taking two samples and discarding the rest of the material, the whole of the stream is divided into six samples by means of the dividing cup D, which is made with six equal segments, delivering by the spouts S into the cases C, one of which only is shown. The *modus operandi* of this apparatus is as follows:—The hopper is set spinning by a touch of the hand, then the sample is thrown in and it is divided into six equal and exactly similar portions in less than the same number of seconds. The economy in time over hand-dividing is at least 98 per cent., and there is the further advantage of precision and cleanliness.

The question of the most convenient way of applying mechanical sampling to various cases will, of course, depend upon the particular conditions of each.

In manufactories, wharves, and mills the machine may be placed at any point where it will intercept a stream of material. In every case it is most desirable to pass the whole bulk through the machine, but where this is not practicable, the first sample (which should be a good size) can be taken by hand and then quartered down in the machine.

Such fertilisers as are made in a semi-liquid form could be, in the author's opinion, conveniently sampled just as it leaves the mixer and falls into the den, and the interposition of a sampler on the annular rotating stream principle would be found to make the contents of the den more uniform. If dry, mixed fertilisers were always prepared upon an upper floor, and then delivered on to a lower one, it would be a great advantage, for the reasons that it could be perfectly sampled while descending on to the lower floor, and at the same time the mixing would be very greatly improved. Against this would have to be put the small cost of elevating the material.

There are many other special cases which time does not permit now to be considered, such as the sampling of grain and foodstuffs, chemicals, ores, and bullion, but these the author would be glad to speak of if necessary.

In conclusion, the author begs to state that he has endeavoured to deal with the subject purely from a practical scientific standpoint, and he ventures to hope that ere long the very important operation of sampling will be lifted out of the rule of thumb into the realm of precision and scientific accuracy.

#### DISCUSSION.

MR. J. CARTER BELL thought this machine would be of great use, now that the Fertilisers and Foods Stuffs Act had come into force. The Board of Agriculture had given directions how these samples had to be taken by dividing them into three parts, and he could not see any better arrangement for sampling manures and seed cakes. He wished that the machine would be able to sample such a material as wood pulp, as it was most difficult to get an uniform sample.

MR. GEORGE E. DAVIS said that in a discussion which took place in this Society some time ago upon discrepancies in sampling and analyses, the feeling was generally expressed that most of the differences between analyses arose from the

varying composition of the samples submitted. If they were so, the introduction of a machine like that before them would be of great service, not only to the sampler, but also to the chemist, who was often blamed without sufficient cause. He had always held that the discrepancies between various analysts would disappear the moment a perfect sample or series of samples could be procured for independent examination. At the same time the sampling machine, to be a perfect one, must be capable of sampling all sorts of materials, large and small, and of every degree of physical condition. It would not do if it could only be used for granular substances, and not for materials of a pasty nature. It would be easy enough to take a sample of, say small pyrites or purple ore, but not so easy to sample by the machine before them a mixture of manure made in a continuous mixer. Then again, such substances as feeding cakes would certainly require some preliminary treatment independent of the sampling machine. Perhaps the inventor would be able to inform the meeting whether these objections were real or not, and if they were real, whether anything had been done to overcome them.

MR. CLARKSON, in reply, said, with regard to pasty materials, the machine would sample any material that could be made to flow. The cone upon which the stream divides was mounted upon a screw. The cone could be very readily raised, and there was only a very thin stream all round, and by this means they could sample oils, &c. When the pasty substances could not be made to flow, they could be forced by means of a ram. Jewellers' sweepings were ground up to the consistency of thick slime, and this was very difficult to sample, inasmuch as it contained little shots of metal which could not be screened out; but by the fixing of two steel blades, which came down to the rotating copper, satisfactory results were obtained. It would not be difficult to sample wood pulp in a granular form, but in breaking it up the percentage of moisture would be rather altered. It all depended a great deal upon the form of the material. He did not see how anything better could be done than the method adopted by Mr. Carter Bell, inasmuch as if it could be made to flow, it could be readily tested. The method adopted in Antwerp for sampling silver ore bars, was to saw each bar across the middle with a circular saw, and from 25 tons you would probably get 180 lb. of sawings of various sizes and weights. It was the custom formerly to cut them down in the usual way, and this took four or five men three-quarters of an hour to do properly. They tried it in one of these machines and found that the sawings of 25 tons could easily be cut down in 2½ minutes.

## FERMENTATION IN THE LEATHER INDUSTRY.

BY J. L. WOOD.

THE leather industry can fairly lay claim to be one of the oldest of all the old arts or crafts. It can truly be said that its beginnings are "lost in the mists of antiquity."

Perhaps one of the earliest references to tanning or dressing of leather is to be found in the *Iliad* of Homer (xvii. 382—393).

He is describing the struggle of the Greeks and Trojans over the body of Patroclus; how they tug—

\* As when a man  
A huge oxhide drunken with slippery lard  
Gives to be stretched, his servants all around  
Disposed, just intervals between, the task  
Ply strenuous, and while many straining hard  
Extend it equal on all sides, it sweats  
The moisture out and drinks the unction in.\*

The process is very similar to that used by savage tribes at the present day, and the description explains almost exactly the principle by which oil or chamois leather is dressed by modern methods.

There are many references in the *Iliad* to leather, or perhaps, to speak more strictly, rudely dressed hide, used in the making of shields. These were of seven thicknesses of tough bull's hide, and made by a clever worker in leather, whose name Homer has handed down to us as Τυχίος σκυτοδόμος δὲ ἄριστος.† Aristotle (Knights, 868—893) makes Demos complain of the abominable smell which emanated from the tanyard of Clon, the sole leather tanner. Other ancient references to leather will be found in Herodotus (v. 58) and in the Bible.‡ Thus more than 3,000 years ago the tanner's art was practised, doubtless in a very similar manner to that which prevailed up to comparatively modern times.

Tanning has, like all ancient industries, become perfect in the course of ages by pure empiricism. The practical man, warned by failures in one direction or another, learned by sheer practice that method which yielded the best results, without troubling himself about the why and the wherefore of it. But the "rule of thumb" processes of tanning have shown themselves in the light of scientific investigation to be of a more complex nature than almost any other industry, hence the difficulty of successfully applying scientific methods to improve on the well-worn processes slowly and painfully evolved during centuries of practice.
